For this entry, Scandinavia comprises the three current day nations of Denmark, Norway, and Sweden. The Baltic Sea ends at the Kattegat (the waterway between Jutland and Sweden) and, in addition to Denmark and Sweden, has shores on the current day nations of Finland, Russia, Estonia, Latvia, Lithuania, Poland, and Germany. Discussion of Russia is generally excluded from this entry and can be found elsewhere in this volume. In terms of cultural groups, "Norse" is used for those speaking Old Norse and excludes the Sámi living across northern Norway and Sweden, as well as northern Finland and the Kola Peninsula in Russia. Outside of Scandinavia, cultural and/or genetic groups are often difficult to locate, and there is uncertainty over the reliability of the tribal names provided by outsiders such as the "Bavarian Geographer" and Tacitus. Finno-Ugric speaking peoples occupied the south of Finland. Baltic Russia came to be controlled by the Rus, a mixed group of Slavs and Norse. Elsewhere along the Baltic rim, there appears to have been populations of Slavs, Finno-Ugrians, and Balts, and the populations moved and mixed over time.

Historical Background

Written sources provide, at best, tantalizing glimpses into those peoples occupying Scandinavia and the Baltic during the early medieval period. Prior to the Viking Age (c. 780–1000) our knowledge is based almost entirely on material evidence, supplemented by the reports of foreigners, later legendary material including the poem *Beowulf* and post-1100 sagas, and the few

Scandinavia and the Baltic Sea Region: Medieval Archaeology, Fig. 1 Scandinavia and the Baltic in the medieval period up to 1000 CE. (Map drawn by Aurore McLeod)

characteristically short runic (the alphabet used in Scandinavia) inscriptions (Fig. 1). There were no written sources produced by those living elsewhere around the Baltic Sea, nor by the Sámi living in the north of Scandinavia and Finland. Although the Viking Age is characterized as a time in which speakers of Old Norse ventured from Scandinavia in large numbers and had an impact on many other parts of Europe, the majority of our written information about them comes from non-Scandinavian sources. For those living elsewhere around the Baltic rim, there is hardly any written information available at all, perhaps in part as those living there were not involved in activities away from home that attracted comment. It has been noted that the first consistent and relatively comprehensive account of the peoples living in Scandinavia and around the Baltic did not occur until the 1070s with the work of Adam of Bremen (Blomkvist 2004), which was partly based on information obtained during a stay at the court of the Danish king Svend Estridson.

Before this, the most detailed accounts were the travel narratives of the Norwegian Ohthere and Wulfstan, possibly an Anglo-Saxon, recorded in southern England in the late ninth century. They report on sailing journeys that stretched from the White Sea (Russia), around the coast of Norway and into the southern Baltic via Hedeby to Truso (Poland). These presumably first-hand accounts provide information on sailing routes, trading places, and the location of different peoples. Recent multidisciplinary publications have done much to enhance our understanding of these voyages, including the archaeology of the regions in c. 900 (Bately and Englert 2007; Englert and Trakadas 2009). The travel reports make plain the ease of water travel within the Baltic and around the coast of Scandinavia during the Viking Age and the subsequent interactions between different peoples.

This dearth of written material for the first half of the medieval period makes archaeology essential to the study of virtually all aspects of the region, which has resulted in a great deal of inter- and multidisciplinary work. Fortunately, the number of sites available has been steadily increasing in recent decades. Important sites of the pre- and Viking Age period include furnished burials, both inhumations and cremation, such as those at Jelling, Hedeby/Haithabu (Denmark), Gamla Uppsala, Vendel, Valsgärde (Sweden), Oseberg, Gokstad, Borre, Tune (Norway), Truso (Poland), Ėgliškiai (Lithuania), and Grobiņa (Latvia); trading sites and central places, often including a cult site, such as Lundeborg/Gudme, Hedeby, Ribe, Aarhus (Denmark), Helgö, Birka, Uppåkra (Sweden), Kaupang (Norway), Grobiņa (Latvia), Reric, Usedom (Germany), Truso, Wolin, Gdańsk (Poland), and Palanga and Žardė (Lithuania); the chieftains farms at Borg in Lofoten (Norway); and fortifications at Trelleborg, Fyrkat (Denmark), and Daugmale (Latvia). Materials recovered from these sites includes weapons, jewelry, coins, and ceramics, both of local manufacture and imports, and buildings, defenses, particularly the 30-km-long earthwork Danevirke across the Jutland that was built in three phases between 737 and 968, sleds, wagons, and items associated with craft production. The site of Borg in Lofoten is an important reminder of how well connected Scandinavia and the Baltic were to other parts of Europe during this pre-/protohistoric period. Although Borg is the most northerly known Norse settlement in Scandinavia and the furthest north that subsistence farming was possible, the finds included a number of prestige objects from the sixth to tenth centuries from southern Scandinavia, England, the Celtic world, and western and eastern Europe (Näsman and Roesdahl 2003). As one would expect, underwater archaeology makes a significant contribution to our understanding, and a number of harbors, jetties, and defensive structures have been uncovered throughout Scandinavia and the Baltic. Of particular note is the Viking Ship Museum in Roskilde, Denmark, which includes local discoveries of Viking Age warships, cargo ships, and a fishing vessel; reconstructed medieval ships from throughout the Baltic Sea; and recently recovered vessels being preserved at the Archaeological Workshop.

The contact between those living in Scandinavia and those living across the Baltic Sea reported by the travel account of Wulfstan is attested in the archaeological record. Material evidence for Norse involvement in the southern Baltic stretches back to at least 650 and the establishment of a Norse population in Grobiņa (Valk 2009). During the Viking Age, Norse involvement elsewhere along the Baltic rim increased dramatically, although in many instances those often referred to as "Rus" or "Varangians" in written sources were simply passing through to reach the eastern trade routes to the Black and Caspian Seas. The routes connected Scandinavia, especially Gotland and Birka in Sweden, with Constantinople and Arabia, often via Staraya Ladoga in Russia. The most tangible evidence of these trade routes is the large numbers of silver dirhams (Arabic coins) found around the Baltic, both in hoards and as single finds, with a concentration of coins on Gotland and mainland Sweden. One anomaly is Lithuania, which has little evidence of Norse trade during the Viking Age (Valk 2009). Some finds, in particular burials with close affinities to some found in Scandinavia, suggest that there were resident communities of Norse in

many of the trading centers in the south of the Baltic, such as Truso and Grobiņa (Jagodziński 2009), while Norse mercenaries may have been living in Poland in the late tenth century (Urbańczyk 2008). The island of Åland and possibly the west coasts of Finland and Estonia had a large number of permanent immigrants from Sweden from at least the Viking Age, and these areas were culturally Norse to varying degrees (Markus 2004; Edgren 2009). Meanwhile, there is written and archaeological evidence, in the form of burials, for a resident Slavic population in Hedeby, and it has been noted that there was a "Widespread maritime Baltic Sea culture linked by the water and similar subsistence strategies and lifestyles" (Markus 2004). There are written accounts of intermarriage between royal families in Scandinavia and elsewhere around the Baltic, and such relations are likely to have occurred at other levels of society. Relations between the different communities settled in trade centers appear to have been cordial, but there are instances of Norse attacks on Baltic trade centers. The troubled times on both sides of the Baltic are attested by many initially unfortified trading centers either being fortified or abandoned for fortified ones during the ninth and tenth centuries, such as Wolin, Usedom, and Hedeby (Jöns 2009). Similarly, Viking Age and post-Viking Age settlements in Estonia were inland, probably due to the dangers presented by the Norse sailing along the coast (Valk 2009).

The period immediately following the Viking Age was in many respects a continuation from the earlier period: Norse fleets dominated the Baltic, allowing them to control trade and attack trade centers. The most dramatic example of the latter is probably the attack by the Norwegian King Magnus the Good against Wolin in 1043 which indirectly, in conjunction with the degradation of the local environment, led to the demise of what had probably been the largest trade center in the Baltic Sea (Broich 2001). But in other respects, it was a period characterized by religious change and state formation, although both of these also had their roots in the Viking Age, especially in Norse Scandinavia. Following centuries of influence, evidenced by some Christian objects being found in burials, and some unsuccessful missionary attempts, Christianity had a significant impact from the late tenth century, beginning in the western Baltic and spreading east. The Danish king Harald Bluetooth converted in c. 965 and convinced or forced his people to follow, as he proudly proclaims on his runestone at Jelling, and the Polish king Mieszko I was baptized in c. 966, although pagan practices among the populace continued for some time. Norway converted in the early eleventh century, while Sweden had a Christian king at the same time, but Christianity and Paganism probably coexisted for at least another century. Poland was the only area along the south Baltic to convert to Christianity without a foreign invasion. The archaeological evidence for conversion and Christianization is most readily seen in changing burial customs and the building of churches. The conversion of Scandinavia also had an impact on the non-Christian parts of the Baltic as Norse kings began to focus their attention on the Baltic instead of the west. For example, the Danish king Svend Estridson involved himself in the Lutici (Polabian Slavs in Baltic Germany) civil war in 1057, and Swedes conquered much of Finland during the twelfth and thirteenth century. Yet at the same time, some Slavic people appear to have migrated to Denmark, as suggested by the appearance of Slavic pottery from the eleventh century and some Slavic place-names (Naum 2012).

The conversion of those living in Scandinavia and the Baltic (predominantly) by the Latin Church has been termed "Europeanization" and involved the imposition of the Catholic World system in the region (Blomkvist 2004). Material evidence for the various pre-Christian religious beliefs is best attested through burials and pendants, including Thor's hammers for the Norse, but temples/cult sites and statues of gods are also known, including at Jaromarsburg on the Baltic island of Rügen (Germany) and on the west bank of Lake Tissø (Denmark) and a possible open-air sacrificial site at Frösö (Sweden). Following largely unsuccessful missionary efforts to covert Balts and Slavs, crusades were launched by the Teutonic Order from Germany during the thirteenth century against various pagan peoples

around the Baltic including the Slavs of Prussia and the Lithuanians, with the latter crusade being particularly drawn out and bloody and ultimately unsuccessful. The crusaders also came into conflict with Christian Poland. Earlier, Danes, Germans, and Poles had been involved in the Wendish Crusade against the Plobian Slavs in 1147, and Germans and Danes participated in the Livonian (modern-day Latvia and Estonia) Crusade which began in 1198. The crusades were often accompanied by a colonization effort, particularly in Prussia where the Teutonic Order created around 100 cities and 1,400 villages, resulting in a great amount of material culture (Ekdahl 2005). These foreign invasions effectively made indigenous state formation like that experienced in Scandinavia and Poland (intermittently) all but impossible, although Lithuania managed to survive intact and actually expanded during the crusade (Blomkvist 2004). Important archaeological sites include crusader castles at Karksi, Viljandi (Estonia), Grudziądz and Malbork/Marienburg (Poland), and Pöide church (Estonia). A new development has been an investigation of the ecological impact of these castles and how the crusaders and those who followed transformed the surrounding landscapes.

A major development as part of the Europeanization process was the establishment of the Hanseatic League, a trade network centered on Lübeck (Baltic Germany), by German merchants collaborating with the missionary effort (Blomkvist 2004). The league was involved in armed conflict with trade rivals. This led to the domination of the Baltic trade by German merchants from the thirteenth century to the end of the medieval period and also saw German migrants settling in cities along the east Baltic coast. Material evidence for the Hanseatic League consists of surviving gabled architecture in member cities such as Lübeck, Riga (Latvia), and Reval (present-day Tallinn in Estonia) and shipwrecks of Cogs, a distinctive type of ship only found in areas controlled by the League or under its influence (Smith 2010).

From the period around 1000, an increase in trade led to the formation of new trade centers (Fig. 2), while some earlier Scandinavian centers, including Hedeby, Birka, Uppåkra, and Kaupang, were abandoned and were effectively replaced by the new nearby towns of Schleswig, Sigtuna, Lund, and possibly Tønsberg, respectively. Other important new towns, or those that grew from humbler settlements, post-1000 not mentioned above include Oslo, Bergen, Trondheim (Norway), Stockholm, Visby (Sweden), Copenhagen (Denmark), Kiel, Stralow/Stralsund, Rostock (Germany), Memel/Klaipēda (Lithuania), Turku (Finland), Ventspils (Latvia), Königsberg/Kaliningrad, and Beryozovskoye/Primorsk (Russia). As all of these cities still exist, the opportunity for extensive excavation is necessarily limited.

Key Issues/Current Debates

Ethnicity and the associated territorial identification is a particular problem, and classic methods of identifying territory in terms of material culture are often difficult to apply. Of course, this method itself is a continuing source of debate among archaeologists (Jones 1997). In the southern Baltic, the material culture of the Slavic people in the early medieval period was transregional, making it difficult to break the early medieval era into periods, and it has been suggested that many archaeologists use the term "tribal" uncritically (Urbańczyk 2008). In Scandinavia, there are often significant regional differences in such things as the use of runestones and other aspects of material culture, and in some regions both cremation and inhumation burials were occurring at the same time, suggesting different regional identities if not ethnicities (Svanberg 2003a; Sindbæk 2008). Yet at the same time, there appears to have been a pan-Scandinavian use of material culture among the Norse elite and an acknowledgement of supra-regional identities (Svanberg 2003b; Sindbæk 2008).

A key barrier to our understanding of Scandinavia and the Baltic during the medieval period is that many of the excavations are in the form of rescue archaeology, and there are large areas with little economic development that remain largely unexcavated. Other finds that may occur

Scandinavia and the Baltic Sea Region: Medieval Archaeology, Fig. 2 Scandinavia and the Baltic: new foundations after c. 1000 CE. (Map drawn by Aurore McLeod)

are those made by metal detectorists, although the legal requirements differ between the countries. Metal-detecting is effectively banned in Sweden, legally difficult in Denmark and Norway, and a license is required in Poland and Germany. Elsewhere in the Baltic, metal-detecting is easier, leading to enthusiasts from elsewhere visiting those regions. Along with other issues involving metal-detecting, such as a loss of context and find location, this raises the issue of items not being reported and ending up on the black market. As a maritime region, the lack of excavations is compounded by the difficulties involved in locating new underwater sites. A powerful reminder of the gaps in our knowledge is the failure thus far to locate with certainty the trading center of Vineta/Wineta that is thought to have been on the Baltic coast in either Germany or Poland. The descriptions of the port in medieval written sources suggest that it may have been the largest urban center in the Baltic, if not Europe, in c. 1000.

Future Directions

The issue of personal and group identity has been mentioned above, but throughout the medieval period in Scandinavia and the Baltic, it must also be considered in light of the material and written evidence for migration, both between and within Scandinavia and the Baltic, and from further afield, especially of German merchants and Crusaders. How these peoples interacted and what new identities may have been created is a fruitful area for future research. So too are the interactions between the Sámi and their neighbors in Scandinavia, Finland, and Russia. The use of migration theory, which suggests such things as motivations for migration, information networks, and duration, is also likely to lead to new avenues of research.

A field that is likely to revolutionize our understanding of migrant populations at different times is that of genetics. Previously, there have been difficulties in obtaining uncontaminated samples from ancient skeletons, leading to samples from modern-day populations being used and scholars projecting back. However, it now appears that usable genetic samples from ancient skeletons can be obtained (Töpf et al. 2006). Such samples could be used in conjunction with stable strontium and oxygen isotope analysis from ancient teeth (which allows the location/s of a person during childhood to be determined) and the associated material finds, to provide a more detailed understanding of migrant populations and the creation of group and individual identity. The initial challenge will be to obtain a quantifiable sample of ancient skeletons from new excavations.

Significant improvements in our understanding of the eastern Baltic have occurred since the fragmentation of the Soviet Union, which has allowed scholars in the former Soviet states to investigate their past without political "supervision." The political changes have also facilitated the exchange of research and ideas with colleagues from other countries. This is likely to continue as cultural and linguistic barriers are broken down (Ekdahl 2005). An example of these new possibilities is the Institute of Baltic Sea Region History and Archaeology which has existed since 2003 and is based at Klaipēda University in Lithuania. Collaborators include scholars and institutions from Lithuania, Poland, Germany, Sweden, Russia, Latvia, and Denmark.

Scandinavia/Northern Europe: Historical Archaeology

Vesa-Pekka Herva
University of Oulu, Oulu, Finland
University of Helsinki, Helsinki, Finland

Introduction

The regional term Scandinavia/Northern Europe can be defined in different ways but is used here to

refer to the present-day Nordic countries which include the Scandinavian states of Denmark, Norway, and Sweden, along with Iceland and Finland. The Faroe Islands and Greenland are autonomous parts of the Danish realm, whereas the Åland Islands in the Baltic Sea comprise an autonomous province of Finland.

The beginning of the historical period in the Nordic world is conventionally set around the turn of the second millennium CE. However, the number of Scandinavian written documents is rather limited especially before the fourteenth century, and many regions – as well as many aspects of culture and society – are poorly known from documentary sources well into the late medieval and even postmedieval period. The famous medieval sagas of Iceland represent an early development of historical narrative in the Nordic world.

The transition to the historical period in the Nordic world was associated with Christianization and the formation of the Scandinavian kingdoms of Denmark, Norway, and Sweden. Southern parts of Scandinavia became urbanized and integrated into wider European economic, social, and cultural networks by the fourteenth century, whereas traditional ways of life and thought persisted in more peripheral regions. While Denmark was the dominant Scandinavian power especially in the medieval period, Sweden established itself as a great power in the seventeenth century. Sweden acquired new provinces in addition to its old province of Finland and came to dominate the Baltic Sea region after its successful intervention in the Thirty Years' War (1618–1648), but the Swedish empire collapsed at the beginning of the eighteenth century.

Archaeological research into the historical period Nordic world began in the nineteenth century, and large-scale (rescue) excavations have been conducted since the mid-twentieth century, especially in association with urban redevelopment in historic towns. While the initial interest in churches, palaces, and other high-status or special sites continues, the scope of research has broadened to include all kinds of sites from medieval hamlets to modern ruins, and research topics and approaches have similarly diversified. Traditional descriptive and cultural-historical approaches are still in evidence, but theoretical perspectives have been combined with empirical research increasingly since the 1990s.

Definition

Historical archaeology can be defined in several slightly different ways. In the most general sense, historical archaeology refers to the archaeological study of the historical period which began around CE 1000 in Scandinavia and slightly later in Finland. Historical archaeology can also be understood in methodological terms as a form of archaeology which employs literary and documentary sources (e.g., written narratives, tax records, probate inventories, maps) together with archaeological data. Thus conceived, Nordic historical archaeology includes also the study of Iron Age societies with the help of later documentary sources. The term historical archaeology may also be associated, due to US influence, with the global archaeology of the post-Columbian world, though such usage is not common in the Nordic countries.

Rather than a unified field of study, historical archaeology in the Nordic countries is divided into several chronological and thematic subfields. As elsewhere in Europe, the study of the medieval period has dominated historical archaeology, whereas postmedieval archaeology is a somewhat less established field, albeit of growing interest. On the other hand, the conventional chronological boundaries between the Iron Age and Middle Ages and the medieval and early modern period are also being increasingly ignored in current research.

Thematic specialisms are plentiful in Nordic historical archaeology and include, for example, urban, rural, and maritime archaeology as well as church, industrial, and conflict archaeology. General texts on historical archaeology in the Nordic countries are not available, which in part probably reflects the compartmentalized or dispersed character of the field. Thematic surveys of narrower topics, such as urban archaeology, have been published, but those also vary in scope and geographical and chronological coverage. Although studies in Nordic historical archaeology have

tended to have a regional focus and/or concentrate on particular (types of) sites or classes of material culture, broader perspectives and theoretically informed approaches have been increasingly emerging over the last two or so decades.

While medieval sites are considered protected heritage in the Nordic countries, the heritage status of postmedieval sites is more problematic and subject to discussion and debate. Teaching is given and research conducted in historical archaeology at archaeology departments around the Nordic countries. Additionally, Lund University in Sweden has a chair in medieval archaeology and Aarhus University in Denmark a section for medieval and Renaissance archaeology. There is, at present, little unity in Nordic historical archaeology with regard to research topics or the methodologies and theoretical frameworks employed.

Key Issues and Current Debates

Three broad themes are considered below which illuminate various aspects of historical archaeology in the Nordic countries. A brief survey is necessarily selective and a number of other topics could also be considered central to Nordic historical archaeology. For example, Christianization and the archaeology of churches and other ecclesiastical sites have been of much interest and caused debate for over a century. Maritime archaeology with its many dimensions, from the excavation of shipwrecks to the study of coastal landscapes, could similarly be identified as a key issue, although it is referred to only in passing below.

Urban Archaeology

Urban archaeology is one of the main fields of historical archaeology in the Nordic countries. The interest in urban sites reflects, first, the significance of towns in large-scale transformations of Nordic societies from the early medieval to the industrial period, that is, the Europeanization and modernization of the Nordic world. Second, urban sites have been subject to extensive fieldwork due to urban redevelopment since mid-twentieth century, which has produced rich and large assemblages of archaeological data. Important excavations have been conducted in, for example, Lund in Sweden, Trondheim in Norway, and Turku (Åbo) in Finland.

There were a few urban-like central places in Scandinavia during the Viking Age, but urbanization really began with state formation early in the second millennium CE. There were some 175 towns in the Nordic world in the Middle Ages, concentrated mainly in Denmark and southern Sweden. There were important towns also in Norway, a few in the Swedish province of Finland, and none in Iceland. All medieval towns were located in southern parts of Scandinavia, that is, south of the Trondheim-Gävle-Ulvila (Ulfsby) line (see further, e.g., Andrén 1989).

Archaeological interest has traditionally focused on earlier phases of towns, and the research has sought, for example, to reconstruct changes in urban space in relation to broader economic, political, and other historical developments. In addition to conventional cultural-historical approaches, theoretically aware interpretive approaches to built environments have been adopted since the 1990s especially in Sweden but also in other Nordic countries (e.g., see various papers in Ersgård et al. 1992; Andersson et al. 1997; Immonen et al. 2007). Such studies have often focused on social and power relations and how they were expressed in urban or other built environments. For example, the research on the extensively excavated Archbishop's Palace in Trondheim, Norway, has provided insights into the relationship between monumental architecture and power from the late medieval period to the Reformation. The research has explored how changes in the organization and structure of the palace, and craft production within it, were dynamically linked to historical processes and how the architecture of the palace mediated broader social and cultural transformations in the turbulent times of the medieval-early modern transition (Saunders 2002).

Hanseatic trade and German influence on Scandinavia have attracted much interest in Nordic medieval archaeology. German merchants controlled trade in the Baltic Sea and arguably had a major impact on the development of Nordic

urban culture (see, e.g., Gaimster 2005). The intensification of trade and German influence is in evidence not only in towns but also in more peripheral regions beyond the urban zone, as manifested in, for example, increased coin finds and emergence of market places in the northernmost coastal region of the Baltic Sea.

Early modern towns are also being archaeologically studied, especially in Sweden and Finland. The seventeenth century was a time of urban development in the kingdom of Sweden. A number of new towns were founded by the Crown in previously nonurban regions, and old towns were reorganized in grid plan, following Renaissance ideals of urban planning. Research has been done, for example, in Göteborg in southwestern Sweden and the small town of Tornio (Torneå) in northern Finland. Archaeological study of postmedieval towns is very limited in Denmark and Norway, but some research has recently been conducted on eighteenth-century deposits in Copenhagen harbor (Høst-Madsen 2005). Some research has also been undertaken in the capital of Iceland, Reykjavik, founded in the late eighteenth century.

Colonization and Colonialism

Although the historical core areas of the Nordic world are located in the southern and western parts of Scandinavia, the north and its resources attracted increasing interest since the early medieval period. Farming settlement spread toward the north from the early second millennium onward. The medieval expansion of farming settlement into northern parts of Sweden and Finland is poorly known archaeologically, although some important sites have been studied. For example, the site of Kainuunkylä-Hietaniemi just south of the Arctic Circle on the Swedish-Finnish border has produced evidence of an early phase of the southern colonization of the north. There was also a market place and non-Christian burials at the site (Wallerström 1995).

Although the northern periphery lacked actual towns, there were market places across the northern fringe of Europe. Archaeological research has been conducted at, for example, Gásir in Eyjafjörður (Iceland), Vågan in Lofoten (Norway), and Haminasaari in Kemi (Finland). Recent research on the so-called multiroom houses in northernmost Arctic Norway has also produced interesting results on economic intensification and intercultural contacts in northernmost Europe during the medieval period (Olsen et al. 2011).

In addition to fish and fur, northern mineral resources were also of interest to the Scandinavian states. The great mine of Kopparberg in Falun, south-central Sweden, is a particularly famous medieval and early modern mining complex, and today a UNESCO World Heritage site, but mines and forges were also established in the northern fringes of the Swedish realm, and the sites of Silbojokk and Kvikkjokk in Swedish Lapland have also been archaeologically studied. Archaeological research has also been undertaken on later mining communities elsewhere in Sweden (e.g., Svensson et al. 2009).

Archaeology of the Modern World

The transitional period between the medieval and early modern period, from the fifteenth to seventeenth century, is today an accepted part of Nordic historical archaeology as something of a chronological extension to medieval archaeology. Fieldwork at urban and other multi-period sites, for example, has produced archaeological material also from later historical periods which has so far been little studied, although there are important exceptions (e.g., Rosén 2004; Lucas 2009). Archaeological research focusing specifically on the postmedieval processes of modernization and modernity is relatively scanty but attracting increasing interest (e.g., Lihammer and Nordin 2010).

Although the modern world has until recently received limited attention within Nordic historical archaeology, younger industrial and military sites in particular have been documented and excavated for some time. In Finland, for instance, the national heritage agency has documented WWI fortifications around the Finnish capital, Helsinki, and fieldwork has occasionally been conducted also at WWII sites. Although the fieldwork at modern sites has often been motivated by cultural heritage management, academic research is now

also engaging with twentieth-century military sites. For example, some research has recently been done on the landscapes, materiality, and archaeology of WWII German sites in Finland and Norway (e.g., Seitsonen and Herva 2011). Likewise, the study of modern ruins from an archaeological perspective has recently begun in Norway and Iceland.

Future Directions

Future challenges in Nordic urban archaeology will include, for example, understanding how changes in urban environments were linked to broader transformations in ways of life and thought in early modern towns. The local character and diversity of urban life also remain to be properly appreciated; urban experience in southern urban centers was presumably quite different from small peripheral towns (cf. Herva 2010).

While aspects of trade have been central to Nordic urban and historical archaeology, consumption studies have also emerged since the 1990s. The consumption models initially adopted from Anglo-American historical archaeology may not be directly applicable to the early modern Nordic world, and especially its more peripheral regions. The importance of the local cultural background and context of consumption is being increasingly appreciated today, as indicated, for instance, by recent research on artifact biographies in the seventeenth-eighteenth-century town of Tornio (Herva and Nurmi 2009) or the ceramic revolution in nineteenth-century Iceland (Lucas 2010).

Equally, although Sámi archaeology is an established field of study in Norway, Sweden, and Finland, researchers have yet to truly engage with the Sámi past in terms of colonialism, and within the framework of the archaeology of colonialism, which has emerged as a key topic in current world historical archaeology. Specifically, the expansion of farming settlement and the exploitation of northern resources resulted in increased contacts with the indigenous Sámi who inhabited northern parts of Fennoscandia and became subject to Scandinavian colonialism. The southern colonization and colonialism of northern Fennoscandia came to have a long-standing impact on the Sámi which is still felt today in many ways, including a continuing debate on land ownership in traditional Sámi homelands and the repatriation of Sámi cultural heritage (e.g., Mulk 2009). Much more research on the archaeology of these processes is needed, however.

Sweden and Denmark engaged also in global colonial pursuits, albeit in small scale. Denmark came to dominate Iceland and Greenland and established colonies also in Africa and the Caribbean, whereas the most well-known (albeit short-lived) Swedish colony was established in Delaware. Limited archaeological research has been done on Scandinavian overseas colonies, but they have recently become of increased interest among Nordic archaeologists (e.g., Immonen 2012; Nordin 2012).

Finally, the archaeology of the contemporary and recent past is a new branch of study in Nordic historical archaeology, but a Swedish language introduction to the field has recently been published (Burström 2007). Although still a contested field, the increasing archaeological study of the later historical times suggests a degree of liberation from the so-called tyranny of historical sources which has always overshadowed historical archaeology in the Nordic countries and beyond. Theoretical advances in archaeology and material culture studies have provided historical archaeology with new perspectives and approaches for addressing issues which are pertinent to the emergence and development of the modern world in the last half-millennium. In all these areas, the historical archaeology of the Nordic countries can offer "a view from the periphery" on modernization and its archaeological study.

Scandinavia: Field Methods

Stefan Larsson
Swedish National Heritage Board, Lund, Sweden

Introduction

Scandinavian archaeology has been influenced by three important factors: its embrace by the state, its terrain, and its methodological innovations. The position of Scandinavian archaeology within the state administration descends from the frequent, long, and bloody conflicts between Denmark-Norway and Sweden-Finland. The number of monuments that could be claimed was instrumental in the diplomatic game of the day: the most venerable history gave a higher ranking at peace negotiations. In short, Scandinavian archaeology is the offspring of an "antiquarian arms race." The Danish legal tradition goes back as far as medieval times: all "treasure" found is the property of the King, while in the Swedish tradition, which has been a reference for both the Norwegian and Finnish legislation, sites and monuments belong to the state. Sites and monuments are to be protected or, if this not being possible, recorded professionally, thus making it a public responsibility to maintain a body of archaeologists. The overwhelming majority of excavations

Scandinavia: Field Methods, Fig. 1 A large-scale excavation of the medieval village of Örja, just outside Landskrona, Sweden (Photo by Thomas Hansson, Swedish National Heritage Board)

are performed within this legal administration, resulting in large-scale archaeological projects, today aided by digital recording (Fig. 1).

Key Issues/Current Debates/Future Directions/Examples

Archaeological deposits in Scandinavia vary from Paleolithic deposits and large Mesolithic dwelling sites of the Ertebølle culture, to the heaped clay Bronze Age burial mounds of Jutland ("the mound people," Glob 1974), to large-scale settlements, votive deposits in bogs, ship burials, shipwrecks, and large-scale central places of the Iron Age to early trading and manufacturing centers of the Viking Age. In upland areas, settlements and burial mounds remain visible above ground level. In lowland areas, they have been located by intensive surveys (Welinder 2009).

Scandinavian innovations include the development of typology, large-scale survey, and different approaches to excavation. Typology became something of a Scandinavian speciality, starting with C.J. Thomsen's (1788–1865) presentation of the "three-age system," i.e., the division of prehistory into the Stone, Bronze, and Iron Ages, which was developed indirectly from the taxonomy developed by C. Linnaeus and his disciples. The system was gradually refined during the course of the nineteenth century by, among others, J.J Worsaæ (1821–1885), S. Müller (1846–1934), and B.E. Hildebrand (1806–1884). Particularly influential was the concept of chronological evolution to explain the changing forms of artifacts by O. Montelius (1843–1921) (Fig. 2).

Since all archaeological remains were (and are) regarded as the cultural property of the state, large-scale surveys pursued the goal of total record. This has empowered geographical methods of historical analysis, such as Bjørn Myhre's early medieval kingdoms in Norway, drawn by Thiessen polygons from hierarchies of burials, ship-sheds, and hill forts (1987), and Åke Hyenstrand's use of Sweden's Ancient Monuments Register for tracing regions and socio-economical systems (Hyenstrand 1984).

In excavation, Scandinavian archaeologists have been influenced by both the German approach, which divides a deposit into horizontal and vertical slices ("schnitt"), and the British, which gives primacy to the stratification. However, it was the pioneering work of Gudmund Hatt and C.J. Becker in the 1930s and 1940s that led to the development of large-scale open area excavations. These were applied in particular to prehistoric and medieval settlements where survival may be little more than postholes and ribbons of small stones left by turf and timber buildings. These techniques were taken up in Britain and spread widely in Europe. On site pioneering methodologies by Scandinavian

Scandinavia: Field Methods, Fig. 2 Oscar Montelius (1843–1921) used the evolution of carriages, from horse drawn to railway, to illustrate how artifacts develop through time. The method allows an artifact type, and assemblages of artifacts, to be assigned to a particular period

archaeologists include the excavation of huge preserved timber ships and their contents from mounds at Gokstad and Oseberg (see Gansum 2004), the recovery and analysis of bog bodies (Asingh and Lynnerup 2007), and the lifting of an entire *burial chamber* at Medelpad, Sweden, in 1952. Modern pioneers have been contributing in particular to the development of methods of electronic *remote mapping*.

Scanning Electron Microscopy (SEM): Applications in Archaeology

Ellery Frahm
Department of Archaeology, University of Sheffield, Sheffield, South Yorkshire, UK

Introduction

Scanning electron microscopy (SEM; this acronym is used for both the instrument itself and the technique) has been broadly used in archaeology for over four decades. The SEM is capable of two basic functions: imaging and providing compositional information. Consequently, it has been utilized for nearly every archaeological application in which one wishes to examine magnified images of a specimen and/or determine its composition on a microscopic scale, everything from determining the raw-material sources of stone tools to examining the five-millennia-old skin of Ötzi the Iceman.

All SEMs permit one to acquire highly magnified images of a specimen. The range of magnifications possible is much greater with SEM than with visible-light microscopy (VLM). Depending on the instrument, the magnification can be adjusted as low as 5X (equivalent to a hand lens) and as high as 200,000X (roughly 100 times better than a powerful VLM) or more. SEM also offers a much greater depth of field than VLM (roughly 300 times better), meaning that more of the specimen will appear in focus.

Most contemporary SEMs are also outfitted to measure the elemental composition of the specimen based on the X-rays emitted under electron bombardment. A closely related technique, which developed alongside SEM, is electron microprobe analysis (EMPA; this acronym is also used for the instrument). Figure 1 illustrates the major systems of SEM and EMPA.

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 1 Simplified schematic of a typical SEM and EMPA. The beam (purple) is generated in the electron column (orange) and focused onto a specimen (brown) in the chamber (tan). The secondary-electron (SE) detector is green, and the backscattered-electron (BSE) detector is red. X-rays from a specimen are measured by an energy-dispersive spectrometer (EDS; yellow) and, in the EMPA, wavelength-dispersive spectrometers (WDSs; blue). (Image by Ellery Frahm)

Definition

At the top of the SEM is an "electron gun," which produces a beam of electrons and accelerates them toward a specimen. The electron beam is focused onto a specimen by a series of apertures and electromagnetic lenses. The beam rasters across the specimen to produce an image, much like a CRT-based television set. This process ordinarily occurs under a high vacuum to avoid beam scattering by air molecules and other effects.

When the electrons strike a specimen, a wide variety of information-bearing signals is produced. Some of these signals are useful for imaging. Others may be used for compositional or microstructural analysis, provided the appropriate detectors are present.

One imaging signal is the emission of secondary electrons (SEs). SEs have low energies, so only those emitted within nanometers of the specimen surface can escape. Therefore, SEs are sensitive to the specimen's topography and are useful for imaging surface details. Many people have seen examples of these images: microscopists frequently use SE images of spiders, table salt crystals, or pollen as examples of SEM images.

Backscattered electrons (BSEs) offer another way to image a specimen. BSEs are beam

electrons that have "ricocheted" out of the specimen. They have much higher energies than SEs and are less affected by topography. Instead, BSEs are strongly affected by the atomic number of the elements in a specimen. The dependence on atomic number is used to produce images that show compositional contrast (although there is also a topographic component to BSE images for non-flat specimens). BSE images have bright areas where the mean atomic number is higher and dark areas where it is lower (Fig. 2).

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 2 A BSE image shows the interfaces between two distinct glasses used to manufacture an East Java mosaic bead. The glass that contains lead oxide as an opacifier appears lighter in this image. The field of view is 2 mm across. (Image by Ellery Frahm)

Contrast in BSE images, though, reveals only relative differences in composition. The elements present cannot be identified without measuring their X-ray emissions. Characteristic X-rays have wavelengths and energies unique to the elements from which they are emitted, and they are measured using X-ray spectrometers to determine a specimen's elemental composition.

Modern SEMs are commonly outfitted with energy-dispersive spectrometers (EDS) to measure such X-rays (Fig. 3). EDS is also sometimes abbreviated as EDX, EDXA, or the trade name EDAX. In SEM-EDS, one searches for and measures the intensity of characteristic X-rays at energies which correspond to elements within a specimen. EDS spectra, though, suffer from overlapping X-ray peaks for some elements, and the system is usually not sensitive enough to measure the tiny signals produced by trace elements.

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 3 A BSE image of a ceramic sherd (Khabur ware from Tell Mozan, Syria) and the EDS spectra of three mineral inclusions. The field of view is 8 mm across. (Image by Ellery Frahm)

S

Characteristic X-rays are measured differently in electron microprobe analysis (EMPA). An electron microprobe is outfitted with several wavelength-dispersive spectrometers (WDS). EMPA-WDS differentiates X-rays by wavelength, rather than energy, for more precise measurements. Like an SEM, a microprobe has also EDS, and it can acquire highly magnified images of a specimen.

SEM-EDS and EMPA-WDS are both spot techniques, meaning the electron beam is focused on a spot and elemental composition is measured for only a small volume, just a few cubic micrometers, not the full specimen. This permits one to obtain highly localized data and to analyze specimens so small that they cannot be studied using other techniques. It also permits one to measure the elemental variation across a specimen surface. Thus, SEM-EDS and EMPA-WDS are well suited to study mixtures, that is, specimens with mixed components (e.g., ceramics, glasses, rocks, slags). Element distributions can be mapped using SEM-EDS or EMPA-WDS, yielding an image constructed from a grid of X-ray measurements (Figs. 4, 5, and 6).

Nonconductive specimens (i.e., nonmetals) must be coated with an ultrathin layer (about 100 Å) of a conductive material, normally gold or carbon, to prevent an electric charge from building up on the specimen surface. This coat can be later removed from many specimens.

Historical Background

The earliest commercial SEM model, the Stereoscan, was developed at Cambridge University and sold by Cambridge Scientific Instrument Company. The first batch in 1965 consisted of five instruments. Within 3 years, 100 SEMs were sold each year. It was at this time that paleoecologist Jonathan Pilcher (1968) published one of the first papers to apply the technique to archaeology. In particular, he used SEM to observe and identify pollen as a means of ecological reconstruction. The next year, archaeologist Don Brothwell (1969) at the British Museum discussed the advantages of SEM for examining such archaeological materials as ancient bone and teeth, fibers, botanical remains, and lithics.

By 1985, about 13,000 SEMs had been sold worldwide, and the technique was frequently used to observe the archaeological materials discussed by Brothwell. A year later, the "Scanning Electron Microscopy in Archaeology" conference was held at the University of London, and the proceedings were published in a book edited by Sandra Olsen (1988). Due to advancements in SEM over the last two and a half decades, particularly regarding hardware and performance as well as data processing, these 1986-era papers are showing their age and nearing obsolescence.

Key Issues

Recent Developments

The instruments discussed at the 1986 London conference date to the 1970s and early 1980s, and SEMs have advanced considerably since the publication of Olsen (1988). For example, most of the backscattered-electron (BSE) detectors in that volume are now obsolete. In a modern SEM, there is a newer type of dedicated BSE detector that offers images superior to those one will see in older publications. Secondary-electron (SE) imaging has improved due to the development and popularity of a new type of electron gun. This new electron gun, known as a field-emission gun (FEG), enables higher-resolution imaging due to an even smaller beam diameter. As a result, the resolution in a modern research-grade SEM is about 2 nm, an order of magnitude better than two decades ago.

Digital imaging is another major advancement. In earlier decades, photographs were taken of high-resolution CRT screens. Now images are captured, stored, and processed digitally.

Another recent development is imaging at reduced vacuums (i.e., closer to atmospheric pressures), called environmental SEM (ESEM; also sometimes called variable-pressure SEM). Additional air within the specimen chamber reduces the electrical charging of nonconductive specimens so that coating with carbon or gold is often unneeded.

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 4 Element maps of the same area as Fig. 2. These maps show how the two glasses differ in the concentrations and spatial distributions of six elements. The lighter areas have a higher concentration of the element than the darker areas. It is clear that one of these glasses contains lead oxide as an opacifier, whereas the other glass does not. (Images by Ellery Frahm)

The last few years have seen the introduction by several manufacturers of so-called "tabletop" SEMs. These instruments currently are not what microscopists would consider "research grade," but their lower purchase and maintenance costs as well as their smaller sizes and relative portability are quite attractive for archaeological applications. As a trade-off, their capabilities are limited (e.g., magnification) and highly variable from model to model. Only a few tabletop SEMs have EDS systems.

In addition, SEM-EDS is often used today in conjunction with other analytical techniques not readily available to archaeologists in 1986. SEM-EDS (and EMPA-WDS) data, for example, are often used to calibrate LA-ICP-MS measurements.

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 5 An example of how element maps can be combined into red-green-blue (RGB) maps to highlight compositional differences in a specimen. The sherd and area shown are the same as Fig. 3. When overlaid, these maps show the abundance, variety, and distributions of different minerals as well as elemental variations within the clay itself. (Image by Ellery Frahm)

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 6 An RGB element map shows the compositional differences between the slip and paint on this sherd (the same ware as Figs. 3 and 5). The map also reveals a series of incised lines not apparent to the naked eye. (Images by Ellery Frahm)

Current Applications

SEM-EDS is one of the most versatile analytical techniques in archaeology, applicable to the study of a wide range of inorganic and organic artifacts and archaeological materials. Only a very few of these applications can be considered here.

SEM imaging and analysis is experiencing a renaissance in all fields of archaeological obsidian studies. Geochronologists often use SEM-EDS and EMPA-WDS to analyze volcanic glass shards and chemically match them to a specific volcanic eruption. This dating procedure, called tephrachronology, is quite similar to obsidian sourcing, so it is not surprising that SEM-EDS can also be useful for analyzing obsidian. After brief experiments with mixed results during the 1980s, archaeologists have recently returned to SEM-EDS as an obsidian sourcing technique. Due to advancements over the last two decades, the results have been promising, especially in the Western Mediterranean (Le Bourdonnec et al. 2006). SEM has been suggested as a way to improve obsidian hydration dating by eliminating the problematic reliance on VLM (Kayani and McDonnell 2008). It has also been utilized for use-wear analyses of Mexican obsidian scrapers (Mandujano et al. 2002).

Artificial glasses, which are typically mixtures, are also well studied by SEM-EDS. For example, Heck and Hoffmann (2000) used this technique to analyze the glass matrix and identify the colorants and opacifiers of Merovingian beads. Bronk and Freestone (2001) took advantage of this spot-analytical technique to analyze submillimeter-sized fragments sampled from glass artifacts with only minimal damage. Weathering and corrosion of Sassanian glass artifacts from Iraq have also been investigated using SEM-EDS (Gulmini et al. 2009).

As mixtures, ceramics are well suited to characterization using SEM-EDS. For instance, SEM-EDS allows tempering materials, such as sands, to be characterized (Fig. 7). Ownby and her colleagues analyzed schist temper in Hohokam ceramic wares and distinguished between schist that naturally occurs in sand and clay versus crushed schist deliberately added as a temper (Ownby et al. 2004). Thin pottery glazes can be studied, and their components, such as opacifiers and colorants, can be identified (Charalambous et al. 2010). Wolf (2002) used SEM-EDS to investigate the production technology of medieval Swiss bricks through examination of their microstructure and mineralogy.

Metallurgy is also well studied by SEM. For example, Giumlia-Mair and her colleagues investigated the Bronze Age metallurgical traditions of the al-Midamman culture in Yemen and contrasted them with Near Eastern traditions (Giumlia-Mair et al. 2000). Experimental alloys, designed to mimic ancient metals, have been examined (Constantinides et al. 2001). Slags can also be characterized by SEM-EDS and the metallurgical processes that produced them identified (Fig. 8), and the analysis of metal ores can complete the picture.

Rocks, minerals, and their products, such as lithics and pigments, can also be studied using SEM. Bustillo and her colleagues used BSE imaging and EDS analysis to classify cherts used in Neolithic Iberia (Bustillo et al. 2009). The

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 7 RGB element maps of sand from Bahrain, Giza, and Petra. Silicon is red, calcium is green, and iron is blue. Examination in the SEM or EMPA reveals differences in the sediment composition, sorting, and roundness. (Image by Ellery Frahm)

Scanning Electron Microscopy (SEM): Applications in Archaeology, Fig. 8 Excavation of a historic site near downtown Minneapolis turned up slag specimens, which came as a surprise because maps indicate the area was a residential neighborhood during the nineteenth century. Analyses revealed that it was slag from a puddling furnace. Puddling removes excess carbon, silicon, and other impurities from pig iron to make wrought iron. This causes loss of iron to the slag, so the glassy matrix of the slag is iron rich. Iron is green, carbon is blue, and silicon is red. The field of view is 500 μm across. (Image by Ellery Frahm)

imaging capabilities of SEM have been used to study use-wear traces and also investigate lithic reduction techniques. For example, traces of a copper-based point used for pressure flaking have been found on chert blades in the Indus Valley (Méry et al. 2007). Layers of mineral-based pigments and plasters can also be studied with an electron beam that can be focused to microscopic sizes (Damiani et al. 2003).

A wide variety of biological materials, too many to list, can also be studied using SEM. Identifying pollen was one of the earliest archaeological uses (Pilcher 1968). This continues to be a popular application, especially when combined with charcoals and other microbotanical evidence to reconstruct the vegetation history and thus paleoclimate of a region. Teeth and bone are frequently examined by SEM to study diagenesis, pathologies, and other phenomena. Coppa and his colleagues identified in vivo drilling of human teeth using flint tools in Neolithic Pakistan (Coppa et al. 2006). SEM examination of eggshell fragments can permit species identification, and using this technique, Beachan and Durand (2007) found evidence of turkey husbandry over eight centuries ago in the American Southwest.

Future Directions

The future of SEM in archaeology will most likely involve (1) the availability of new detector systems to investigate new problems and (2) advances in "tabletop" SEMs. Regarding the first issue, a system already available on certain SEMs detects the beam electrons that diffract out of a specimen due to its crystalline structure. This phenomenon is known as electron backscatter diffraction (EBSD), and it is just now starting to be applied to archaeological specimens (Peruzzo et al. 2011). Its clearest advantage for archaeologists is being able to distinguish in situ minerals with the same elemental composition but different structures and origins, for example, calcite from limestone or aragonite from shell, both $CaCO_3$ and indistinguishable using EDS in isolation. It is possible that in the future new detectors will be developed that combine the speed of EDS with the precision of WDS.

Regarding the second issue, future "tabletop" SEMs will have fewer limitations than current models and will become even more portable. SEM-EDS and EMPA-WDS were developed during the 1970s, in part, as a way to nondestructively analyze lunar rocks, and new instruments will likely take advantage of research to miniaturize SEMs for future Mars rovers. Just as it seems more practical for NASA to send an SEM to Mars than to bring specimens back to Earth, it will eventually be more practical for archaeologists to bring portable SEMs into the field rather than export artifacts to a laboratory halfway around the world.

S

Schávelzon, Daniel

Victoria Pedrotta
Departamento de Ciencias Naturales y Antropología y Fundación Azara, Universidad Maimónides, CONICET, FCNyM-UNLP, Buenos Aires, Argentina

Basic Biographical Information

Born in Buenos Aires, Argentina, in 1950, Daniel Schávelzon earned a degree in architecture in the

Faculty of Architecture and Urbanism of the Buenos Aires University (1975). He earned a Master (1981) and Doctorate in Architecture (1984) at the National Autonomous University of Mexico (UNAM). Back in Argentina since 1984, currently, he is higher investigator at the National Council for Scientific and Technological Research (CONICET) and professor at Museo Social Argentino University and at the Faculty of Architecture, Design and Urbanism of Buenos Aires University, where he is the head of the Center of Urban Archaeology. Schávelzon is the director of the Area of Urban Archaeology of the Buenos Aires City Government; emeritus historical adviser of the National Commission of Historical Museums, Monuments and Places; and member of the Academy of History of Buenos Aires and of the ICOMOS Argentine Committee.

He teaches graduate courses and conducts seminars in Argentina and other Latin American universities and frequently serves as mentor, as well as undergraduate and graduate advisor. He has presented more than 180 papers in scientific meetings and gave nearly 170 lectures.

Schávelzon is the author of about 40 books, 200 scientific and divulgation articles, tens of pamphlets and exhibition guides, as well as innumerable mass media articles. His scientific production and his contribution to the preservation of the cultural heritage have received distinctions, scholarships, and prizes both in Argentina and abroad.

Major Accomplishments

The initial years of Daniel Schávelzon's career were dedicated to the study of Mesoamerican pre-Hispanic architecture, mainly in Mexico on subjects of conservation and restoration (Schávelzon 1992). After his return to Argentina, after the military dictatorship ruling the country between 1976 and 1983 was overthrown, Schávelzon's research focused on a new and until then practically unexplored area: Urban Archaeology (Zarankin y Salerno 1997). In 1986, he founded the current Center of Urban Archaeology in the Faculty of Architecture, Design and Urbanism of Buenos Aires University, leading an interdisciplinary group of specialists that has carried out archaeological investigations not only in Buenos Aires city and its vicinity but also in other Argentine cities, with the subsequent study of the archaeological collections (Centro de Arqueología Urbana n.d.). Among others, the Ezcurra House, the Coni Printing House, the Convent of Santa Catalina, Tres de Febrero Park, the Government House and the Town Hall, and several tunnels and underground constructions in Buenos Aires city should be mentioned (Schávelzon 2000a, 2005, among others). Other relevant investigations include the areas of the early foundation of the cities of Mendoza and Puerto Deseado.

Schávelzon has been a precursor in the conservation and analysis of artifacts (ceramics, clay pipes, glasses, metals, etc.) from post-Hispanic archaeological contexts (sixteenth to twentieth century). His publications represent important contributions, and his catalogs are remarkable references (Schávelzon 1991, 2000b, 2001, 2003, among others).

Schávelzon has stimulated the collaboration with research centers of several Argentine provinces and has promoted the formation of local research teams, inspiring the growth and diversification of Historical Archaeology in Argentina and its relations with other Latin American countries (Funari 1997; Gómez Romero 2005; Politis 2003). His assiduous activities in favor of scientific divulgation in newspapers, radio, television, and more recently Internet contribute to increase both general knowledge and public interest about Urban and Historical Archaeology (Schávelzon 2008, n.d.).

Schiffer, Michael Brian (Modern World)

Michael Brian Schiffer
School of Anthropology, University of Arizona, Tucson, AZ, USA

Basic Biographical Information

I was born in Winnipeg, Manitoba, Canada, on October 4, 1947, to Louie and Frances-Fera Schiffer. In 1953 we moved to Los Angeles, where I grew up. My parents enjoyed a happy marriage for 63 years and provided a loving home. Neither parent had finished high school, but both were avid readers and instilled in me a love of learning and the expectation that I would attend UCLA.

At UCLA I took classes from Sally and Lewis Binford, James Hill, and James Sackett. During the summer of 1968, prior to my senior year, I attended Paul Martin's summer program at Vernon, Arizona, whose staff included Fred Plog, Mark Leone, and Ezra Zubrow. These undergraduate experiences familiarized me with processual archaeology, which I expected to practice in graduate school. On December 22, 1968, I married Annette Leve, who remains my lover and best friend. Annette and I have two sons, Adam Joseph and Jeremy Alan, of whom we are very proud.

Turning down generous fellowships at Michigan and UCLA, I attended graduate school at the University of Arizona. During graduate studies, I became disenchanted with the processual approach to inference and, especially, its inept handling of the formation processes of the archaeological record. Also while a graduate student, I collaborated with J. Jefferson Reid and William Rathje to create the research program known as behavioral archaeology, which privileges the study of relationships between human behavior and material culture in all times and all places. These emphases resulted in a Ph.D. dissertation (1973) that became, after much revision, *Behavioral Archaeology* (Schiffer 1976).

In my first job, with the Arkansas Archaeological Survey, I learned about Cultural Resource Management (CRM) from Charles McGimsey and Hester Davis. This experience eventuated in a monograph (Schiffer and House 1975) and book (Schiffer and Gumerman 1977). Some say that these works had a salutary effect on CRM projects in the United States by demonstrating the necessity of conducting cutting-edge research in a management context.

In 1975 I returned to the University of Arizona as assistant professor. Among my first projects was an overview, with Randall McGuire, of the prehistory of southwestern Arizona (Hohokam and Patayan 1982) and a study of reuse processes in modern Tucson; I also became interested in experimental archaeology and ethnoarchaeology and continued work on formation processes.

Major Accomplishments

One of my proudest accomplishments was editing, beginning in 1978, 23 annual volumes of archaeological method and theory stretching over three series and three publishers: *Advances in Archaeological Method and Theory*, *Archaeological Method and Theory*, and *Journal of Archaeological Method and Theory*.

I was promoted to associate professor in 1979 and 3 years later to professor. In 1983 James Skibo and I built the Laboratory of Traditional Technology, dedicated to experimental studies and equipped with tools for making pottery. Our experiments led to more than a dozen publications (e.g., Schiffer and Skibo 1987) and decisively turned my research interests toward technological change. The publication of *Formation Processes of the Archaeological Record* (Schiffer 1987) closed that chapter of my career.

During the mid-1980s a hobby – collecting portable radios – turned into a study of that artifact's history, which furnished insights into social, economic, and technological change (Schiffer 1991). Next was an early history of the electric automobile (Schiffer et al. 1994). The radio and automobile studies addressed, respectively, then-current issues in American society: the hollowing out of manufacturing and a possible electric car revival.

During the 1980s, postprocessual archaeology stridently attacked processual and behavioral archaeologies. Beyond criticizing the antiscience, intellectual relativism of early postprocessual statements, I encouraged students to engage from a behavioral standpoint the postprocessual research topics such as ritual and religion, symbolism, and social power. My own response was to fashion an artifact-based theory of communication (Schiffer and Miller 1999) and with William Walker an artifact-acquisition perspective on social power.

Curious about the earliest electrical technologies, I first tackled the eighteenth century (*Draw the Lightning Down*: *Benjamin Franklin and Electrical Technology in the Age of Enlightenment*, *2003*) then the nineteenth (*Power Struggles*: *Scientific Authority and the Creation of Practical Electricity Before Edison*, *2008*). Both books, which exemplify my best scholarship, challenged from a behavioral standpoint many interpretations crafted by historians. Although the subjects of these books may seem distant from the concerns of prehistoric and even most historical archaeologists, the projects were an opportunity to conduct a kind of ethnoarchaeology that employs historical evidence. Given the copious documentary and published materials available on both the technologies and their behavioral contexts, I fashioned widely applicable generalizations about technological change, which I aimed at archaeologists in a half dozen articles and a book (2011). Drawing on my studies of technology and more traditional topics, I also wrote a "Reader's Digest" version of behavioral archaeology (Schiffer 2010).

In 2004 my colleagues elected me the fourth Fred A. Riecker Distinguished Professor of Anthropology.

Schiffer, Michael Brian (Theory)

William H. Walker
Department of Anthropology, New Mexico State University, Las Cruces, NM, USA

Basic Biographical Information

Michael Brian Schiffer (Fig. 1) was born on a small farm in Winnipeg, Manitoba, Canada, on October 4, 1947. He moved with his family in the early 1950s to California growing up in the Crenshaw district of south-central Los Angeles. As an undergraduate, he attended the University of California at Los Angeles. Initially he majored in chemistry but changed to anthropology in his sophomore year. He graduated with a B.A. in Anthropology in 1969. As an undergraduate, he was steeped in New Archaeology; his professors included James N. Hill, James Sackett, Lewis R. Binford, and Sally R. Binford. In the summer of 1968, he joined the Chicago Field Museum of Natural History's Southwest Expedition to east-central Arizona directed by Paul Sidney Martin and assisted by Fred Plog, Mark Leone, and Ezra Zubrow.

Schiffer, Michael Brian (Theory), Fig. 1 Michael Brian Schiffer in 2012. (Photo by Annette Schiffer)

Schiffer entered the doctoral program in Anthropology at the University of Arizona in 1969 and conducted his dissertation work at the Joint Site in the Mogollon Rim country. He received an M.A. in 1972 and Ph.D. in 1973. His doctoral dissertation, entitled *Cultural Formation Processes of the Archaeological Record: Applications at the Joint Site, East-Central Arizona*, laid the foundation for his subsequent scholarship as a behavioral archaeologist. Upon graduation, he took a job with the Arkansas Archaeological Survey for 2 years. In 1975, he returned to the University of Arizona as an Assistant Professor of Anthropology. He was promoted to Associate Professor in 1979 and Full Professor

in 1982. Upon William A. Longacre's retirement in 2004, he was elected Fred A. Riecker Distinguished Professor of Anthropology.

In 1983, Schiffer and his graduate student, James M. Skibo, established the Laboratory of Traditional Technology at the University of Arizona. This facility is dedicated to studying experimentally the effects of technical choices on the performance characteristics of artifacts, especially ceramic artifacts. Some of their most important collaborations include their article "Theory and Experiment in the Study of Technological Change" (Schiffer and Skibo 1987).

Major Accomplishments

Michael Schiffer is one the founders of Behavioral Archaeology, a social science research program that defines human behavior as interaction between people and objects (artifacts, architecture, and other people). In the beginning of his career (Schiffer 1976, 1987), Schiffer focused on developing behavioral method and theory to describe and explain archaeological patterning. This included creation of behavioral chain analysis and a synthetic model of inference (Schiffer 1975). As one of the cofounders of the subdiscipline of behavioral archaeology, along with William Rathje and J. Jefferson Reid, Schiffer has consistently developed method and theory that places material objects at the center of behavioral studies of human activity (Reid et al. 1975).

Building on the basic definition of human behavior, Schiffer developed a synthetic model of inference (Schiffer 1976) that takes into account the behavioral and natural processes that create the archaeological record. The synthetic model of inference drew together various sources of actualistic knowledge, including ethnography, ethnoarchaeology, history, and experiments, to create generalizations that could be used in inferences about unknown relationships between past peoples and objects. Such a model necessarily assumes continuities between past and present relationships: (1) the sequential nature of behaviors forming objects' histories, (2) the causal contribution objects make to behaviors that propel the forward motion of activities in life histories, and (3) four kinds of measurement that make possible the empirical study of object performances and life histories (Schiffer 1987).

To call attention to the generalizations concerning artifact disposal activities and subsequent archaeological patterning, Schiffer (1976) coined the terms n- and c-transforms, which denote the effects that natural and human (or cultural) processes have on the formation of archaeological deposits. Correlates, another kind of behavioral generalization, pair dimensions of measurable artifact variability (frequency, formal properties of materials, locations in three-dimensional space, and associations in space between objects) to the organization of behaviors (people-object interactions).

As his career has progressed, he has extended behavioral method and theory across a range of disciplines and has extensively explored human-object interactions in the history of technology, modeling of behavioral processes involved in the invention, development, manufacture, and adoption of technologies (Schiffer 2010, 2011). Several models and constructs have been critical to this endeavor, including the analysis of performance characteristics and performance matrices, which were developed in collaboration with James M. Skibo (e.g., Schiffer and Skibo 1987; Skibo and Schiffer 2008). Performance characteristics, such as heating effectiveness in cooking pots, are capabilities or competences that objects bring to interactions that allow them to take place (cooking) and facilitate the forward motion (feasting) of behavioral events. The rise and spread of new technologies often involves competitions among performance characteristics in different stages (e.g., manufacture, use) in the life histories of artifacts comprising technologies. Use of performance matrices enabled Schiffer to explore the electric automobile in the late nineteenth and early twentieth centuries as well as the history of electric lighthouses (Schiffer et al. 1994; Schiffer 2008). More recently, he completed two studies of the history of electrical science and technology spanning the eighteenth and nineteenth centuries (Schiffer 2008; Schiffer et al. 2003).

Finally, the placement of artifacts at the center of behavioral study has allowed Schiffer to

ground seemingly immaterial topics in material-behavioral perspectives. One of the most interesting such treatments has been Schiffer and Miller's (1999) artifact-focused approach to human communication. Inspired by the process of information transmission implicit in the synthetic model of archaeological inference, Schiffer and Miller retasked this model for the behavioral study of communication. Their approach differs from more traditional ones by highlighting the important roles artifacts play in the process and by reversing the analytical emphasis from senders of information to receivers.

S

Schliemann, Heinrich

Stefanie A. H. Kennell
Vancouver, BC, Canada

Basic Biographical Information

International entrepreneur and self-taught archaeologist Heinrich Schliemann (1822–1890), whose excavations are widely credited with discovering the Greek Bronze Age, was born in Neubukow (Mecklenburg, Germany). The son of a clergyman

who lost his rural parish for immorality (1831) (Traill 1995), Schliemann attended the Neustrelitz *Realschule* (1833–1836) before becoming a grocer's apprentice (1836–1841) and studying bookkeeping. Shipwrecked off Holland while en route to Venezuela (late 1841), he found work in the import–export business in Amsterdam and began to learn foreign languages. Employment with B.H. Schröder & Co. in 1844 inspired him to learn Russian. In early 1846, he moved to St. Petersburg as agent for several firms, soon founding his own company to sell commodities such as indigo, cotton, coffee, and sugar. In 1850, his brother's death took him to California, where he made large sums buying gold dust. Back in St. Petersburg in 1852, he married Ekaterina Petrovna Lyshin, a lawyer's daughter by whom he had a son and two daughters. His wealth grew during the Crimean War (1853–1856) as he imported commodities like sulfur, saltpeter, and lead. From 1856, Schliemann turned to banking and the study of the ancient world. He toured Europe, Egypt, the Levant, and Athens (1858–1859) and traded in tea (1862–1864) before exchanging commerce for round-the-world travel. In 1866, Schliemann attended a variety of scholarly lectures in Paris, returned briefly to Russia, and settled in Paris by year's end to enjoy literary-intellectual pursuits funded by investment income. In 1867–1868, he traveled to North America and Cuba, Italy, Greece, and the Troad. In 1869, he published his first archaeological book, inspired by fieldwork in Greece and Turkey, received a Ph.D. from the University of Rostock, obtained US citizenship and a divorce, and married the 17-year-old Athenian Sophia Engastromenos, who bore him a son and a daughter. Concern for Sophia's well-being caused his permanent move to Greece in 1871. Schliemann died in Naples, Italy, on 26 December 1890 of complications from ear surgery.

Major Accomplishments

At Troy, Mycenae, Orchomenos, and Tiryns, Schliemann discovered remains of a prehistoric civilization, which he dubbed "Mycenaean" after Homeric epic (Calder and Cobet 1990). During campaigns at Troy between 1870 and 1890, he evolved from novice excavator to experienced scholar. At Mycenae (1876), Schliemann and his wife excavated several tholos tombs, including the "Treasury of Atreus," and Grave Circle A's famous shaft graves. At Orchomenos (1880, 1881), Schliemann cleared the ruined "Treasury of Minyas," noting the distinctive pottery now called Gray Minyan Ware. Excavations at Tiryns (1876, 1884, 1885) uncovered Cyclopean walls and a palace complex featuring frescoes and a bathroom.

Despite the famous treasures of Troy and Mycenae, Schliemann preferred artifacts that led to substantive scientific results; his awareness of stratigraphic method and materials analysis antedates his collaboration with Wilhelm Dörpfeld. His choice of photographs to illustrate the Troy finds was innovative though unsuccessful, his multilingual excavation publications exemplary. With prehistoric archaeology in its infancy, identification and dating errors were inevitable, but his expertise grew through experience and consultation (Kennell 2010).

Relations with officialdom were often strained. His removal of artifacts led to a lawsuit by the Turkish state (1874–1875), and he resisted supervision by the Greek Archaeological Service at Mycenae. His funding of the demolition of the Frankish Tower on the Athenian Acropolis also sparked controversy. After the Turkish lawsuit was settled, Schliemann traveled around Europe seeking comparative material in museums and investigated other sites in Greece (Levadia, Marathon, Ithaka, Kythera) and Italy (Albano, Motya). On the strength of his work at Troy and Mycenae (Fig. 1), Oxford University awarded Schliemann an honorary doctorate in 1883. In Crete, he vainly tried to obtain land at Knossos and a permit to excavate (1884–1889). He toured Egypt twice, visiting Flinders Petrie. Schliemann collaborated with other scholars and organized international conferences at Troy (1889, 1890) (Fig. 2). He left three monuments in Athens: his house, the Iliou Melathron; the German

Schliemann, Heinrich, Fig. 1 Schliemann in 1883. (Courtesy of the American School of Classical Studies at Athens, Gennadius Library Archives, Heinrich Schliemann Papers)

Archaeological Institute building; and his own mausoleum in the First Cemetery. Over decades, he archived tens of thousands of letters from hundreds of correspondents that significantly complement his publications and diaries (Kennell 2007; *Heinrich Schliemann* papers n.d.).

Schliemann's publications excited scholarly interest and impressed the general public, not least because of his personal voice as entrepreneur, writer, and excavator. Academics and amateurs disparaged his reliance on Homer and Pausanias, along with his chronology and interpretations (Zavadil 2009). Even today, his greatest fame comes from his discoveries at Troy and Mycenae, regardless of the nature and circumstances of his results. With his forceful personality and scientific bent, this ex-businessman redefined archaeology, formerly the purview of academic admirers of Classical aesthetics, as the comprehensive study of the material remains of past civilizations (Herrmann 1992). He combined literary zeal with practical skill to organize, finance, run, and publicize large-scale excavations that initiated the rediscovery of the Aegean Bronze Age. In an age when imperialism was often expressed by nationally funded archaeology, Schliemann's projects were as exceptional in being self-funded, broadly promoted, and internationally disseminated as in their tangible finds (Runnels 2007).

Schmidt, Peter R.

Jonathan R. Walz
Department of Anthropology and Archaeology Program, Rollins College, Winter Park, FL, USA

Basic Biographical Information

Peter Schmidt's impacts on archaeology and African history are theoretical, substantive, and pragmatic. Since the 1970s, his initiatives in Africa have fostered research, institution building, and heritage advocacy. Trained as an archaeologist and historian, Schmidt's approach to archaeology is inclusive, methodologically sophisticated, grounded in structural and symbolic theory, and politically aware (Schmidt 1978, 1983a, b, 1997, 2010; Schmidt and Patterson 1995). His scholarship makes informed representations of Africa and Africans. He highlights the long-term pasts of eastern Africa by integrating material, ethnographic, oral historical, documentary, and environmental sources (Schmidt 1978, 1983a, 1997; for conspectus, see Schmidt 2006).

Born in 1942, Schmidt grew up in northern California and graduated from Stanford University in 1965. He completed his masters degree in African History at UCLA and studied at Makerere University in Uganda with Merrick Posnansky. In 1974, he earned a Ph.D. at Northwestern University, at the time a leading institution of African Studies. Since 1971, Schmidt has been a professor of Anthropology in the United States, including at Brown University (1971–1988) and, his current position, at the University of Florida. His dissertation interpreted Haya kingdoms and the long-term history – technological and otherwise – of northwestern Tanzania using a structural approach to the historical sources of the region. Schmidt's historical archaeology integrated and valorized oral historiographies (Schmidt 1978, 1997, 2006). Thereafter, he worked for a time as the state archaeologist of Idaho, in between his African research and teaching at Brown University. Throughout this period, he continued to practice ethnoarchaeology and experimental ethnoarchaeology as well as to investigate the complex symbol systems of African iron technology. Schmidt's scholarship challenged preconceived notions about African technological inferiority and suggested an independent origin for iron technology on the continent (Schmidt 1997). For popular audiences, *The Tree of Iron*, an award-winning film, recounts the principal findings.

Schmidt's prominence in African Studies and anthropological archaeology expanded during the middle 1980s, when he founded and led the Archaeology Unit at the University of Dar es Salaam in Tanzania (1985–1987). Subsequently, Schmidt spearheaded efforts to establish a human rights center in Uganda and his research on iron technology expanded to Gabon and Cameroon. In 1988, Schmidt joined the University of Florida, serving as director of the Center of African Studies until 1995. As early as 1998, Schmidt began to develop a new stream of research in Eritrea. While in Eritrea, Schmidt served as Dean of the College

of Arts and Social Sciences at the University Asmara and as Chief Curator of Archaeology at the National Museum of Eritrea. Based on detailed archaeological survey and excavations in the vicinity of Asmara, he and his team concluded that the Aksumite Empire developed out of the indigenous Ona culture in the first millennium BCE, rather than arising exclusively or primarily from South Arabian influences (Schmidt et al. 2007).

Major Accomplishments

Throughout his career, Schmidt has worked effectively to overcome the conventional separation of history and "prehistory" to examine historical representations and social memory in Africa (Schmidt 2006). More recently, his interests turned to the play of tropes in archaeological interpretations, the anthropology of time and time concepts, community approaches to heritage in Africa, and the postcolonial integration of archaeology and African history into university pedagogy as an act of political liberation. Schmidt's research, teaching, and publications continue to shape and promote informed historical representations of Africa, Africans, and their pasts.

Schmitz, Pedro Ignacio

Jorge Eremites de Oliveira
Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil

Basic Biographical Information

Pedro Ignacio Schmitz (Fig. 1), priest of the Society of Jesus, is one of the oldest, most renowned, and most awarded Brazilian archaeologists still at work. He was born on the 30th of August 1929, in the city of Bom Princípio, state of Rio Grande do Sul, Brazil, descending from a family of small farmers of European origin and Catholic formation (Magalhães 2011). He thought about becoming a historian at the beginning of his career, but under the guidance of the anthropologist, botanist, and geographer Balduíno Rambo (1906–1961), also a Jesuit, Schmitz chose the Archaeology as his main field of work (Teixeira et al. 2002; Teixeira 2006; Schmitz 2007; Martins and Rogge 2012).

Schmitz, Pedro Ignacio, Fig. 1 Pedro Ignacio Schmitz, picture displayed in his *Curriculum Vitae*. (Available at http://to.plugin.com.br/jag-part-inschmitz.htm (Accessed 16 September 2012))

He holds degrees of Philosophy (1952–1954, from Faculdade de Filosofia Cristo Rei), History and Geography (1955–1958, from Universidade Federal do Rio Grande do Sul – UFRGS), and Theology (1959–1963, from Pontifícia Faculdade de Filosofia e Teologia de Cristo Rei). He concluded his doctorate degree in History and Geography in 1976 from Pontifícia Universidade Católica do Rio Grande do Sul (PUCRS) with the thesis entitled *Sítios de pesca lacustre em Rio Grande, RS, Brasil* ("Archaeological Sites of Lake Fishing in Rio Grande, Rio Grande do Sul, Brazil"), recently republished (Schmitz 2011), study that earned him the title of full professor at that same university (vide Curriculum Vitae at http://lattes.cnpq.br/1125239815915680).

He received training in archaeology in Brazil and several other countries in the Americas and Europe and participated in courses taught by José Loureiro Fernandes (1903–1977) and Annette Laming-Emperaire (1917–1977), among other renowned archaeologists. Betty J. Meggers (1921–2012) and Clifford Evans (1912–1985) invited him to participate in the "Programa Nacional de Pesquisas Arqueológicas" (PRONAPA –acronym in Portuguese for "National Program for Archaeological Research"), developed in Brazil between 1965 and 1970, but he declined the offer. Nevertheless, he adopted the culture-historical proposal of the project, accepted sponsorship from the couple of American archaeologists from 1965 on, and continued developing archaeological research in several Brazilian states: Bahia, Goiás, Mato Grosso do Sul, Pernambuco, Rio Grande do Sul, Santa Catarina, and Tocantins. He also developed archaeological research in Uruguay and published studies on prehistoric Argentina (Schmitz 2006b; Schmitz 2007; Eremites de Oliveira 2008; Martins and Rogge 2012). His scientific production is very significant quantitatively and qualitatively. Beginning in the 1950s, it comprises hundreds of works, mostly published in Portuguese by the Instituto Anchietano de Pesquisas (IAP), one of the major Brazilian institutions of archaeological research, created in 1956 and currently connected to the Universidade do Vale do Rio dos Sinos (UNISINOS), in São Leopoldo, Rio Grande do Sul, for which Schmitz has long been its greatest name. Among many other studies concluded throughout his academic life, it is worth noting his studies on Guarani language in Paraguay, in 1958, as well as his internship in Archaeology at Universidad Nacional de La Plata, Argentina, between 1970 and 1971. He is thus a pioneer archaeologist of holistic formation, within and beyond the four fields of the boasian lineage, with an intellectual production marked mainly by experiences in the subfield of Prehistoric Archaeology in Brazil. He identifies himself as an archaeologist "of historical and multilinear evolutionist trend" linked to American Cultural Anthropology (Teixeira et al. 2002; Schmitz 2007: 3) (Fig. 2).

He was a professor of anthropology at UFRGS from 1958 to 1985, since the days of the former University of Porto Alegre, institution for which he worked part-time and where he retired. He was also a director of IAP from 1966 to 2009, where he continues with his research, coordinates the

(Martins and Rogge 2012: 258)

Schmitz, Pedro Ignacio, Fig. 3 Areas where Pedro Ignacio Schmitz coordinated programs of archaeological research in Brazil. (Martins and Rogge 2012: 265)

area of Archaeology since 1962, and is the editor of the *Pesquisas* journal, established in 1957 (Schmitz 2006a) (Fig. 3).

He was one of the founders of UNISINOS in 1969, with which he collaborated since 1963, when he began teaching at the former Faculdade

S

de Filosofia, Ciências e Letras, that originated the university. Since then, he has taught the disciplines of Anthropology and Archaeology in undergraduate courses, and since 1987, he has composed of the Post Graduation Program in History (M.A. and Ph.D.).

Since 1969, he is a researcher of the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq – acronym in Portuguese for "National Council for Scientific and Technological Development"). Nowadays, he is as representative before government agencies such as CNPq, Instituto do Patrimônio Histórico e Artístico Nacional (IPHAN – acronym in Portuguese for "Institute of National Historical and Artistic Heritage") and the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES – acronym in Portuguese for "Coordination for the Improvement of Higher Education").

Major Accomplishments

The major contribution of Pedro Ignacio Schmitz to archaeology is linked to research conducted in various regions of Brazil, besides the institutionalization, development, and popularization of the archaeological science; the instruction of several generations of archaeologists, sociocultural anthropologists, and ethnohistorians; and the preservation and appreciation of the national archaeological heritage.

Schmitz was one of the founders of the Sociedade de Arqueologia Brasileira (SAB – acronym in Portuguese for "Society of Brazilian Archaeology"), established in 1980, an entity that he not only came to preside during several periods (1980–1981; 1981–1983; 1989–1991) but also took part in its board of directors in other moments. He also occupied important spaces in public agencies charged of the promotion, support, and authorization of archaeological research in Brazil. Many archaeologists worked under his direct influence in the beginning of their careers: Adriana Schmidt Dias, Altair Sales Barbosa, Ana Luiza Vietti Bitencourt, André Luiz Jacobus, Arno Alvarez Kern, Fabíola Andréia Silva, Irmhild Wüst, José Luis dos Santos Peixoto, Marco Aurélio Nadal De Masi, Maribel Girelli, Pedro Augusto Mentz Ribeiro (1936–2006), Rodrigo Lavina, Sílvia Moeleck Copé, and others who, like me, had a passage at the IAP at the beginning of their professional careers (Eremites de Oliveira 2008). Some other colleagues, as André Osorio Rosa, Ítala Irene Basile Becker, Ivone Verardi, Jairo Henrique Rogge, and Marcus Vinicius Beber, either worked or still work under his coordination in the institution. All these people received certain influence from the epistemological model of PRONAPA. Schmitz has also been keeping himself up to date, by following the new contributions registered in World Archaeology, which can be noticed in his most recent works.

Scholarly Publishing of Archaeology

Mitchell Allen
Archaeological Research Facility, University of California, Berkeley, CA, USA

The publication of scholarly research in archaeology is as old as the profession itself and inextricably linked; archaeological knowledge needs to be shared between scholars to be of value in increasing our knowledge of the past. Over the past two centuries, a stable system of transmitting scholarly information between colleagues through publication was developed, only to be upended in recent years by radical changes in digital technology.

History of Scholarly Publishing of Archaeology

The prehistory of scholarly publishing in archaeology parallels the development of human knowledge about the past. Ancient writers from Herodotus to Sima Qian to Pausanias described both the peoples on the fringes of their known world and their material cultures. Medieval travelers from Ibn Battuta to Marco Polo did the same. With the coming of the western Enlightenment, investigation of the lifeways and material culture of previous eras increased, as did the publications relevant to them. Possibly the most important of these was the 20-volume *Description d'Égypte* commissioned by the French emperor Napoleon after his invasion of Egypt, which, with Champollion's translation of the Rosetta Stone, first introduced literate Europeans to ancient civilizations beyond the classical world.

Prehistory and ancient histories became the pastime of many educated Europeans, leading to the development of antiquarian societies whose proceedings and journals recorded and interpreted local finds. The Society of Antiquaries of London began publishing as early as 1718 and launched its first journal, *Archaeologia*, in 1770. The American Antiquarian Society launched its *Transactions* in 1820 (Willey and Sabloff 1974, p. 38).

European natural historians expanded their travels to encompass the globe, and reports of their travels, usually in book form, both advanced scholarship and created an interest in the past societies among the lay public. The writings of scholars such as Alexander von Humboldt on South America and John Lloyd Stephens and Frederick Catherwood on Central America left longing impressions on both scholars and others.

As the field of archaeology professionalized and created academic societies late in the nineteenth century, each launched publication series and scholarly journals to share knowledge with colleagues. Publication of the *Palestine Exploration Fund Quarterly Statement* began in 1869. *American Journal of Archaeology* and *Excavation Memoirs of the Egypt Exploration Fund* were both initiated in 1885, *Antiquity* in 1927, and *American Antiquity* in 1935. Government agencies responsible for archaeology also published results of their work, such as the Bureau of American Ethnology's *Annual Reports*, which appeared beginning 1879–1880 and included research reports from Frank Hamilton Cushing, John Wesley Powell, and Cyrus Thomas.

For most of the twentieth century, scholarly publication in archaeology exhibited a stable pattern. Academic journals carried new research supported with mounds of data. Books of two sorts appeared regularly: popular books, often with titles like *Mysteries of the Past* or *The Glories of Ancient Egypt*, and scholarly books that delved into larger-scale issues and cultural histories in greater depth and length. Excavation and survey reports appeared generally through the publications arms of archaeological research institutes, museums, government agencies, and professional societies like the American School of Classical Archaeology in Athens or the American Schools of Oriental Research. As archaeology became ever more popular a topic with the expansion of higher education in the 1960s, textbooks on the two most popular classes – introduction to archaeology and world prehistory – began appearing, many of the pioneering ones written by Brian Fagan. Conference sessions were converted into edited volumes or journal thematic issues on topics of interest, including a long-standing One World Archaeology series from quadrennial meetings of the World Archaeological Congress (WAC), published sequentially by Routledge, UCL Press, Left Coast, and now Springer. A key series of authoritative cultural histories emerged from Cambridge University Press, which still regularly produces new ones and new editions of their classic ones.

The New Archaeology of the 1960s–1980s found its communication podium in Academic Press, which was looking for ways to expand beyond their base in physical sciences by adding "scientific" social sciences (S. Holwitz pers. comm). Led by editors Bill Woodcock and Stan Holwitz, Academic published 132 archaeology titles over these decades and publicized the ideas of a generation of American scholars, including Lewis Binford, Kent Flannery, and Patty Jo Watson, among many others (O'Brien et al. 2005,

p. 186). The European backlash of post-processual archaeology in the 1980s, led by scholars such as Ian Hodder, Michael Shanks, and Chris Tilley, led the ascent of their British publishing houses, Blackwell, Routledge, and Cambridge, into greater prominence in archaeological publishing. Development of electronic publications changed delivery system but not the products for a period of time. The same books, articles, and reports were available but were read online. Keeping this system intact was the academic tenure and promotion reward system, which still favored peer review article and university press books for academic advancement.

The development of cultural resource management (CRM) created yet another stream of academic writing, CRM reports that were delivered to commercial or governmental sponsors. Data driven and limited in scope to meet the requirements of economic development regulations, these reports were often hastily constructed and rarely peer reviewed. These reports were housed in governmental offices, with access to them severely limited, and thus were given the moniker "gray literature." As the need for training materials for the growing legion of CRM workers and firms emerged, a series of manuals edited by Don Fowler, many of them written by Thomas F. King, were issued from AltaMira Press.

Scholarly Publishing in the Twenty-First Century

With the arrival of the twenty-first century, the publishing landscape changed radically. Academic publishing has become a mature industry, with its customer base static or shrinking. For companies to increase their market share, acquiring competitors became a more efficient strategy than organic growth. Thus, some of the better-known commercial presses publishing archaeology were swallowed up by larger competitors: Academic Press by Elsevier, Plenum by Springer, Berg by Bloomsbury, and Left Coast by Routledge. The same is true with journals: Plenum's group of archaeology journals are now with Springer and Maney's collection now part of Taylor & Francis (T&F). The result is a small number of gigantic commercial presses controlling a significant percentage of the published works in archaeology. Despite this consolidation, a few small independent archaeology presses still remain in North America and Europe – Casemate Academic (formerly Oxbow), British Archaeological Reports, and Berghahn. A significant number of university presses, such as Cambridge, Colorado, Florida, Arizona, and Texas, still publish a significant number of archaeological titles.

Simultaneously, ever more scholarly material began appearing in electronic form, some posted by archaeologists on websites of their universities or government agencies, more coming from the traditional books and journals controlled by commercial presses, academic organizations, and university presses. While the complex physical nature of archaeological data – photos, line drawings, maps, data tables, and lists of registered finds – at first provided a challenge for online publication, these have become ever easier with improvements in digital technology.

Aggregation and Disaggregation of Content

Large publishing conglomerates used the aggregation of publications and their electronic availability on a single platform to capture ever-larger market share of their key customers, academic libraries. Called the "Big Deal," libraries were offered access to large aggregations of journals, discounting each to increase the value of purchasing the aggregation over individual journal subscriptions. Libraries responded by creating consortia so that the cost of groups of subscriptions would be shared by multiple academic and government institutions. As more and more archaeological organizations partnered with commercial or university press publishers (WAC with Springer, Society for American Archaeology with Cambridge, European Archaeological Association with T&F), they too became part of these journal aggregations. Books were soon added to these collections, so that a library could buy the archaeological "content" of a large publisher for a fixed fee no matter what the original format is. To compete, smaller publishers, research organizations, and university presses used third parties

like JSTOR, Project Muse, or EBSCO to aggregate their content. Soon the escalating prices of these aggregations met resistance – the University of California Berkeley refusing to carry the journals of the Nature group in 2010 (Howard 2010) and the national consortium of German libraries temporarily canceling their subscriptions to all Elsevier journals in 2016 (Schiermeier and Rodriguez Mega 2016).

Content disaggregation affected publication of archaeology as well. The individual publication – book or journal – became less central than the amount of overall content, leading large publishers disassembled their book projects into individual chapters and their journals into individual articles as the unit of access and sale. This led to a strategy of increasing the output of large reference works that contained hundreds of articles that could be obtained individually or as part of a database: encyclopedias, handbooks, dictionaries, and companions. The ten-volume Springer World Encyclopedia of Archaeology, of which this entry is a part of the second edition, is one good example. Even more aggressive was the Oxford University Press, which has published several hundred Oxford Bibliographies on archaeology-related topics and 36 Oxford Handbooks in Archaeology between 2010 and 2017, each handbook containing hundreds of articles on almost every topic in the field. The handbooks became part of the Oxford Handbooks Online, which boasted 750 books and 27,000 articles in 2017, a tempting product for the budget-stressed librarian looking to maximize content. Each of these projects is sold on a subscription basis to libraries.

The Open-Access Movement

The migration to online publishing and the exorbitant price increases associated with publisher consolidation led to a countermovement by scholars to make publications open access, available online for all readers worldwide. The open-access mantra, buoyed by the large technology companies who host open platforms and urge that "information should be free," still rings strong in many parts of the academy. Sustainability is difficult since publication involves costs for editorial work, electronic hosting, publicity of findings, and personnel to manage the journal. A good example of this was the first major English language open-access journal, *Internet Archaeology*, launched in 1996 through grant funds. When the grants ran out, a subscription model for institutions was instituted. Since 2014, the journal has replaced subscriptions with Author Processing Charges (APC), asking authors to subsidize publication costs from their institutions, grant funds, or other sources.

Numerous other open-access journals have been launched since then. In 2017 the Directory of Open Access Journals listed 104 in the discipline of archaeology out of the 10,000 in their database. Many use APCs to pay their costs, like *Science & Technology of Archaeological Research* (*STAR*), sponsored by the Society for Archaeological Sciences and published by Taylor & Francis since 2015.

Open access has led to unintended consequences. First, commercial presses embraced the APC model, allowing scholars who could afford it to convert their articles to "gold open access," thereby adding another revenue stream for their journals in addition to library subscriptions. Second, following the lead of *Public Library of Science (PLoS)* founded in 2001, many large publishers have created omnibus journals, accepting articles from any discipline and, like *PLoS*, publishing huge numbers of articles each year. While this greatly expanded the opportunities for publication journal income depends on the number of articles accepted, so the incentive to say no to inferior articles disappears. Many of these journals suffer from middling quality. A more suspect group of open-access journals do not provide rigorous peer review but will post almost any article on their journal's website for a fee. Labeled "predatory" journals, they are often enticing to scholars facing the publish-or-perish rules of academia (Allen 2018). An American librarian, Jeffrey Beall, created a blacklist of these journals to help scholars and librarians sift through the chaff, now replaced by a similar list from Cabell's, a journal indexing service (Anderson 2017).

Further adding to these complexities is the requirement of government and funding

organizations that the results of research using public or grant funds be available to "the public" in an open repository, called "green open access" and usually hosted by universities or professional organizations. Unfortunately most subscription-based journals will not accept articles for publication that are openly available on the web. Authors have been caught in the middle of these competing claims, either limited by time embargoes before depositing their work in a repository or managing multiple drafts of the same work – one in published form and another in repository form.

Yet another complexity has been with the academic reward system itself, as universities increasingly assess scholars through the Journal Impact Factor, which weighs the importance of the journal in which scholars (and, in the United Kingdom, their departments and colleges) are publishing, though not the value of the articles themselves. This metric favors journals controlled by larger publishers, older in age, larger in subscriber base, and more scientific than humanistic in mission, thus tilting the evaluation of a scholar's work in certain directions.

Among the positive effects of digitization has been the ready availability of older research now out of copyright, which has been digitized and made open access through sources such as Google Books, Project Gutenberg, the HathiTrust, or government agencies. Thus, researchers looking to find works by Aurel Stein, Flinders Petrie, or the Bureau of American Ethnology reports mentioned above can obtain them at several clicks of the computer rather than after a long search through university shelves or used book stores.

Publishing Archaeology Books

Publication of archaeological monographs and site reports has also been transformed by technological and economic changes. While costs of publication have steadily declined by the digitization of the production and printing functions, the shrinking library market has created financial stresses on publishers of archaeological reports and studies. Recent studies indicate that American university presses generate only about 4000 monographs a year, only a fraction of them in archaeology (Esposito and Barch 2017), and the average title costs $40,000 to produce while generating only half that amount in revenue (Maron et al. 2016). Subsidies have become the norm for some of the monographic publishers that remain. Authors are increasingly being asked to produce camera-ready texts and forego royalties as prices for these limited-market volumes spike. Like journals, these books are now being included in content aggregations or are sold by the article. Some monograph publishers, like UC Berkeley's Archaeological Research Facility Series, are being published in electronic version only.

As with most other trends in archaeology, the advent of indigenous archaeology has led to a growth of publications either by indigenous scholars or in partnerships between professional archaeologists and indigenous communities. The Nicholas/Andrews collection *At a Crossroads* (1997) and Joe Watkins' *Indigenous Archaeology* (2001) were the early steps in this area. A WAC-sponsored Left Coast Press series (now Routledge) on *Archaeology and Indigenous Peoples* has been published since 2005. Many indigenous people have built their own publications programs, such as Australian Aboriginal Press in Canberra.

Professional archaeologists have always contributed to the popular literature on the past. Flinders Petrie, like most of his Victorian contemporaries, penned poetry. Magazines from *Illustrated London News* to *Time* to *Smithsonian* regularly feature articles by archaeologists or about interesting archaeological projects. Archaeologists launched their own popular magazines such as *Current World Archaeology*, *Archaeology*, *Kemet*, and *Biblical Archaeology Review*. Popular books by archaeologists and a greater number by professional writers and pseudoarchaeologists have had a regular presence in generalist book stores. Heavily illustrated books about Egyptian pyramids, Greek temples, and Mexican figurines line coffee tables around the world, many of the best from English publisher Thames & Hudson. Possibly the best known popular archaeology book, *Gods, Graves, and Scholars* by CW Ceram, published in 1949, is still in print and has sold five million copies (Holtorf 2005, p. 56). Well-known archaeologists like Colin Renfrew, Brian Fagan, Paul Bahn, and Neil Silberman

are in constant demand for new popular titles. The profession, often disdaining this popularization of scholarship in the past, has recently realized the value of the archaeological story being told by archaeologists. Both the Society for American Archaeology and Society for Historical Archaeology present annual awards for the best popular book on the subject. Guidebooks and articles about how to write popular archaeology have increased (Fagan 2010; Connah 2010; Allen 2002; Van Dyke and Bernbeck 2015).

New Models for Archaeological Publishing

The needs of archaeologists to disseminate their findings to their colleagues, funders, stakeholders, and the public will not disappear, but the methods by which this will take place is likely to continue to broaden beyond the traditional scholarly channels. Each of these audiences requires a separate method of dissemination, which will make the ability of archaeologists to communicate in different formats and at different levels of complexity a crucial professional skill. The archaeological researcher will be expected to speak with equal fluency to groups of school children, adults walking through a museum, their expert colleagues, and the history buff scrolling through Netflix offerings. The need for archaeologists to partner with professional writers and videographers, with university public relations offices, and with archaeological educators will only increase as these competing demands do.

There are already some new communication modes on the horizon that will likely come to dominate scholarly publication.

Digitization and government regulation have led to the growth of digital archaeological archives, where the full corpus of research notes, illustrations, maps, plans, and measurements from a project can be housed for future researchers to use. Tested in the United States first in the 1980s as the National Archaeological Database as a way of allowing researchers to access the archaeological gray literature, it has been replaced by a large handful of repositories for archaeological data such as The Digital Archaeological Record (USA), Open Context (USA), Archaeological Data Service (UK), and Mappa (Italy). As new field projects become harder to approve and fund, and as analytic methods improve, these repositories may become the chief source for research data.

The gradual shrinking of avenues of income from traditional publication led large scholarly media companies to expand their array of publishing services in an attempt to capture and monetize the entire research process rather than just the final published product. Preprint server, a forum to post early drafts of research for review in a non-deterministic setting, was developed in hard science fields by several nonprofit organizations over the past two decades. Recently, the best known of these services was purchased by publishing giant Elsevier. Archival repositories, commonly required by governments and funders, are also being developed or purchased by these multinational media conglomerates. The University of Florida, for example, contracted their institutional repository requirements out to Elsevier in 2016. Scholars are encouraged to house their entire scholarly output from research notes to course syllabi in "the cloud," often controlled by large corporations. This expansion of large publishers into all phases of the research and publication process raises the specter of vertically integrated monopolies, as Amazon has developed in the trade book world. These vertical monopolies may come to dominate scholarly publishing in all fields if not prevented by the concerted efforts of communities of scholars.

The visual nature of archaeological data has made it a natural fit for digital technology. Site websites, blogs, news services, online documentaries, virtual tours of famous sites, 3D imaging, 3D printing, and archaeogaming have all become part of the twenty-first century publication panoply. Virtual tours can be taken of sites ranging from Rome to Petra to Merv. Digital archaeological games date at least as far back as Steve Davis and Vin Steponaitis's *Excavating Occaneechi* in 1998 and were boosted by the development of civilization-building games like SimCity and virtual reality worlds created in Second Life. With the high interest in gaming in younger generations and the visual nature of archaeological work,

these trends should only expand in the future. Most of these media are fluid, allowing for constant updates and changes as the knowledge base changes and increases. Scholars will likely be constantly updating their work. They will also likely be responding to regular critiques of it as these media tend to invite interaction from readers.

But the pace of change in digital media is ever accelerating and impacting the entire archaeological process. Thus the future of scholarly publishing will likely take many more turns over the next few decades and is impossible to predict.

Schuyler, Robert L.

Deborah I. Olszewski
Department of Anthropology and Penn Museum, University of Pennsylvania, Philadelphia, PA, USA

Basic Biographical Information

Born in 1941, Robert L. Schuyler is Associate Professor in the Department of Anthropology (University of Pennsylvania) and Associate Curator-in-Charge of the Historical Archaeology Section (University of Pennsylvania Museum of Archaeology and Anthropology). He received his B.A. in Anthropology from the University of Arizona and his M.A. and Ph.D. in Anthropology from the University of California-Santa Barbara (Fig. 1).

Schuyler has directed several fieldwork projects, including investigations of Potomac River Native American sites from the Contact period (seventeenth to eighteenth centuries); the Sandy Ground, Staten Island, nineteenth- to twentieth-century African-American oystering community; the boarding houses of female factory workers in the town of Lowell, Massachusetts, which was one of the first large cities in America to undergo industrialization in the early nineteenth century; and the short-lived silver mining town of Silver Reef, Utah (c. 1877–1887) (Schuyler 1980, 1991).

His current fieldwork research is the South Jersey Project, which is developing the story of Vineland, New Jersey, from the 1860s to the present, in partnership with the Vineland Historical and Antiquarian Society. His innovative approach in this project is historical ethnography

Schuyler, Robert L., Fig. 1 Robert L. Schuyler. (Photo credit: University of Pennsylvania Museum of Archaeology and Anthropology, photographer Lauren Hansen-Flaschen)

(Schuyler 1988), which combines archaeology, archival documents, oral histories, and the study of living communities; it is a framework for historical archaeology that he describes as "the only archaeology in which the subject matter is still forming." The South Jersey Project is part of a new research domain, the archaeology of the twentieth century, and Schuyler's particular interests are in understanding the processes underlying how an agricultural center of the mid- to late 1800s came to have the largest municipal boundaries in present-day New Jersey.

Major Accomplishments

Schuyler is a founding member of the Australasian Society for Historical Archaeology, the Society for Commercial Archaeology, the Society for Post-Medieval Archaeology, and the Society for Industrial Archaeology, among others. He also is a member of the Society for Historical Archaeology (President, 1982), the Council for Northeast Historical Archaeology (President, 1980–1981), the American Anthropological Association, the Society for American Archaeology, and numerous other national, regional, state, and local organizations.

After arriving at the University of Pennsylvania, he developed a Ph.D. program in historical archaeology based on historical ethnography (see above).

In 2009, he received the J.C. Harrington Medal in Historical Archaeology from the Society for Historical Archaeology for his scholarly (Schuyler 1978, 1999, 2003), educational, and professional activities in the discipline.

Science Communication in Archaeology

Alison Mant-Melville
Department of Anthropology, University of Connecticut, Storrs, CT, USA

State of Knowledge and Current Debates

Archaeology has a long history of generating fascination outside of academia. The interpretation of sites, cultural artifacts, and past human behavior using archaeological methods provides a rich source of material for communicating the human stories behind scientific data. Most archaeologists will be involved in public or media communication at some point in their career. When done effectively, science communication in archaeology benefits both society and the discipline. In practice, effective science communication can be time-consuming and challenging. It requires a different set of skills to those used by researchers when communicating within academia, and archaeologists are not typically trained in public engagement techniques. Although science communication and public engagement are increasingly seen as a vital part of an archaeologist's role, it can still be difficult for archaeologists to balance the time and resources to communicate their work outside of academic circles against the competing demands of their roles.

The definition of science communication used in this article is "the exchange of knowledge between scientific experts and public audiences." Contemporary ideas of "science communication" overlap with those of "public engagement," although some authors distinguish between the two. "Public engagement" is generally meant to reflect a mutual exchange of ideas between members of the public and scientists during their interactions. This contrasts with more traditional ideas of science communication as a one-way dissemination of scientific knowledge that is produced by specialists to a less-informed audience. The broader use of "science communication" in this article incorporates "public engagement" as defined above. It also includes dialogue, engagement, participation, and an understanding of the complex and diverse ways in which information is received and understood (Hilgard and Li 2017). Although science communication can also encompass academic peer-to-peer communication, this article focuses on the importance, implications, and opportunities of communicating archaeology to nonspecialists.

Science communication is a skill that incorporates many components: objectives, messages, audience, and communication medium – be it print, television, radio, public exhibition, lectures, or digital platforms. The goals of science communication are varied and so too are the range of communication approaches. There are many different audiences for archaeological information, each with their own needs, perspectives, and biases (Harding 2007). The role and participation of the audience in any communication activity impact how information is received, understood, and used. In the last few decades, the expansion and uptake of digital technologies have created new communication opportunities but also challenged traditional knowledge hierarchies in both how knowledge is created and disseminated.

Why Participate in Science Communication?

What and how archaeologists communicate impact wider political and public support for research funding and the protection and management of cultural heritage. Effective communication of archaeological knowledge is made more important in the current climate of increasingly

competitive research budgets, the proliferation of misinformation from pseudoscience and fake news, and growing scientific skepticism and distrust of experts. Outside of academia, perception of archaeology's value largely rests on effective communication between archaeologists, the public, and policymakers. Much of archaeology is funded through public money, and archaeologists have a responsibility to consider the value of their work for society. It is now common within grant proposal applications for funding bodies to request that researchers explicitly state the broader societal impacts of their research or to describe intended public communication activities. Science communication encourages archaeologists to think about their work in a new light. How is it relevant to everyday life? What use does it have? How does it connect to current events? Do the results justify the costs? In what ways are the results or method extraordinary? As science communicators, archaeologists are expected to think about how their research is situated socially, economically, and politically.

As science, technology, and the Internet pervade more and more of our everyday existence, many segments of society have shown a greater interest in science and how it connects to their lives. Growing public appetite for scientific knowledge encourages investment in science communication centers and postgraduate science communication courses. Archaeologists can contribute to wider efforts to raise scientific literacy by communicating engaging scientific insights about the past. In so doing, they can help create better-informed publics on a wide range of controversial current issues such as climate change, environmental degradation, evolution, cultural and genetic diversity, technological disruptions, the destruction of monuments, and nationalism. Archaeology is uniquely positioned to engage different publics in science because it is an inherently interdisciplinary field that combines expertise and methods from the social, earth, and physical sciences to tell past human stories through objects and material culture. By sharing what archaeologists do, revealing the marvels of past societies, the everyday life of ancient people, and explaining why it matters today, archaeologists have an important role to play in supporting scientific literacy within society.

Whose job is it to tell scientifically informed archaeological stories? To what extent is it the responsibility of the journalist or the archaeologist to communicate scientific knowledge? The roles and relationship of researcher and journalist are undergoing considerable change, and participation in science communication activities is increasingly viewed as a core part of an archaeologist's job. To do it well, science communication is time-intensive and requires a different skill set to that used in research, teaching, and project management. Regardless of their personal level of enthusiasm for science communication, archaeologists must weigh the amount of time to dedicate to communication activities against the competing demands of their roles. In general, archaeologists are not formally rewarded for communication activities, and they have to justify to their colleagues and institutions the time spent away from research. Science communication activities are often considered less important and less prestigious than "mainstream" research work. This attitude is beginning to change in the face of increasing demands on universities and research institutions to deliver public engagement and as some of the larger funding bodies incentivize and fund science communication projects and training. The personal benefits of being involved in science communication activities are also becoming more widely acknowledged and understood. Participating in science communication can provide skills and career development, enhance the impact of and awareness about research, lead to new research perspectives, raise both personal and institutional profiles, create networking and collaboration opportunities, be a source of additional funding, and aid student recruitment.

Although archaeologists often have the ingredients – knowledge and enthusiasm – for successful communication, scientific training does not often prepare archaeologists with the professional skills to harness them. The standard tools of academic communication (lengthy introductions, technical terms, and methodological detail) learned during training must be set aside to avoid constructing boundaries with, and boring,

audiences (Harding 2007). In public engagement activities, academic writing styles are replaced by an inverted structure. Inverted communication structures prioritize concise explanations of the results, the bigger picture, and the "so what" of the story while employing anecdotes and analogies to convey more complicated ideas without resorting to jargon. As science communicators, archaeologists must learn to balance the need to avoid technical jargon and unnecessary detail against concerns of misrepresentation and oversimplification. They also need to be able to perform different roles in the communication exercise, either as a presenter, consultant, discussion participant, or listener, as is required to fit the project's goals and the role taken by the audience.

Models of Science Communication in Archaeology

Successful communication requires information not only to be disseminated but also to be received and understood by the intended recipients. This entails a clear understanding of the communication goals and the target audience. There are many different publics, with different needs, wants, socioeconomic backgrounds, perspectives, and levels of knowledge and interest about the past. In addition to personal and institutional recognition, some of the many goals for communicating archaeological work outside of academia might include correcting misinformation, building trust in the scientific process, raising awareness of an issue, improving public perceptions of their field, getting people involved civically or politically, or promoting evidence-based policy outcomes. There are a number of possible science communication strategies with different approaches producing different types of engagement (Moussouri 2014).

Science communication has a long history. In the seventeenth to nineteenth centuries, scientists began to consider it their responsibility to communicate knowledge to the public. During this time, the tradition of public lectures and the foundation of various scientific institutions, such as the Royal Institution of Great Britain (1799); the Royal Society of London (1663); the British Association for the Advancement of Science (1831), now the British Science Association; and the American Association for the Advancement of Science (1848), helped to popularize science to an increasingly literate public. Over the last few hundred years, science communication has been through a number of theoretical transformations. In recent decades, it has been strongly influenced by critical theory, postcolonial theory, post-processualism, feminism and the concepts of inclusion, empowerment, engagement, and stewardship. Contemporary ideas of science communication no longer consider value, authority, and the control of narrative to be the priority of "specialists" (Stocklmayer 2013).

Holtorf (2007b) outlined three models of science communication in archaeology – the educational, promotional, and the democratic – that address differing communication objectives. The education model is based on a unidirectional and hierarchical flow of information from knowledge-generating experts to a less-informed audience. This fits with more traditional ideas of science communication in which academic knowledge is privileged above other forms of knowledge and the audiences are treated as passive receivers. Science communication using the educational model assumes a gap, or deficit, in the audience's knowledge that the scientist hopes to correct. As a more elitist and hierarchical mode of communication, it also risks miscommunication from a lack of understanding about the needs and wants of the audience.

In Holtorf's promotional model, science communication is a public relations activity, and archaeology is treated as a brand or business. Promotional models of science communication aim to foster a positive public image of archaeological science to potential "customers" in order to return benefits such as funding and support for archaeological "products" (e.g. monuments, museums, research projects, or heritage legislation). This form of communication is often seen in lobbying or mass media to persuade various publics that archaeology is important and worthwhile (Holtorf 2007a). Mortimer Wheeler, a popular archaeological figure from the early twentieth century, was adept at using this communication rational in the mass media to obtain financial

support for his excavations (Clack and Brittain 2007). Common disadvantages of the promotional communication model are the risks of sensationalizing archaeology, "dumbing-down" content, or oversimplifying the past to an extent that results in misrepresentation.

Under the democratic model, communication is two-way, equal, and participatory. The perspectives of nonspecialists form part of the knowledge creation and dissemination process. Engagement, dialogue, and participation are as important as the education of the audience (Holtorf 2007b). A similar science communication model focuses on the role of the audience as "consultants" in which information flows from the nonspecialist audience back to the practitioners of the scientific discipline. The principles of democratic communication differ quite radically from scholarly styles of communication. Democratic communication treats scientific methods as only one possible way of interpreting the past. It challenges archaeologists to rethink what they do, why they do it, and for whom they are doing it. A challenge for this model of communication is how archaeologists should address all-too-common pseudoscience and sensationalist claims, such as "lost" cities, sunken continents, extraterrestrial explanations for ancient monuments, or evolution denials that contradict widely held academic consensus (i.e. "facts"). If scientific perspectives do not take precedence over other ways of knowing, how do archaeologists contest unreliable or misinterpreted claims, especially those used to support racist, nationalistic, or other negative and divisive sociopolitical statements? While it is possible to challenge misuse of science while maintaining true to the ideal of democratic communication, few archaeologists are well trained to do so.

Strategies for communicating archaeological knowledge can also draw insights from cross-cultural communication. Archaeologists are used to communicating in their own technical language. Most are aware of the pitfalls of using discipline-specific jargon, but it is also important to consider how more common words, widely used in archaeology, can carry implied judgments and values or very different meanings, particularly to people outside academia (Stocklmayer 2013). Word choice can strongly impact the public's perception of the message being delivered, especially among marginalized, indigenous, or descendent communities (Watkins 2006). Word's such as "abandoned," "discovered," "complex," and "Old World" have been used to support dominant, elitist, and colonial narratives that reflect very real and persistent biases in the lives of some groups. Archaeologists must be sensitive to how their discipline has been used in the politics of race, identity, power, and inequality in both the, past and present. The use of language can also be a significant barrier with policymakers. The archaeological language of samples, material analyses, and sediment horizons do not translate into the governmental and legalistic language of policymakers and politicians. Careful word choice and awareness of different value judgment applied to terms are important for communicating a message the way it was intended.

A number of leading archaeologists have discussed the power of narrative storytelling for making archaeological knowledge more accessible and interesting (Hodder 1989; Tilley 1989; Joyce 2008; Dahlstrom 2014; van Dyke and Bernbeck 2015). Narrative structures work by creating an unsolved question, problem, or conflict faced by a cast of characters and then describe the actions they take to resolve it. Narrative structure is considered a key component of effective communication as it is engaging and persuasive. It has been shown to have better recall and ease of comprehension for audiences than many other communication techniques. Storytelling often relies heavily on the use of metaphor and analogy, and these are a useful tool for translating scientific concepts through comparison to everyday ideas. Examples of scientific metaphor and analogy such as greenhouse effect, black hole, butterfly effect, evolutionary trees, and selfish genes are now widespread in popular vocabulary. An inherent risk in narrative storytelling is the ethical issues it can raise in terms of implied value judgments, use of persuasion, and a potential loss of accuracy (Dahlstrom 2014). Despite the widespread use of narrative in others forms of communication, it is

largely avoided in academia for these reasons, although there are undoubtedly situations in science communication where the strengths of narrative outweigh the risks. A bigger barrier in its successful use is that scientists receive little, if any, formal training on how to construct effective narratives.

The models discussed above are just some of the approaches to science communication available to archaeologists. Each have their own set of strengths and weaknesses, but together they provide a complementary set of tools for addressing the varied communication needs in archaeology.

Opportunities and Channels for Science Communication in Archaeology

Communication is a rapidly evolving field. The widespread uptake of online digital technologies has changed the role of "traditional" mass media journalism (TV, radio, newspapers) and how archaeologists engage with different publics. Ongoing technological developments are continuing to create new means and opportunities to communicate and engage. Although the reach of the Internet is unrivaled, the Internet cannot meet all needs of science communicators. Mass media remains an important intermediary between researchers and different publics. Museums and science centers provide in-person and multilayered experiences. Community partnerships and outreach offer deeply engaging, personal, and collaborative modes of communication. These assorted communication channels are increasingly integrated with each other, and science communicators rarely use a single communication channel in isolation. Mass media, the Internet, museums, and community projects all play a role in developing new approaches to science communication. Each channel serves different, often complementary purposes, audiences, content, and styles of communication.

Online communication channels include blogs, discussion sites, videos, social media apps, and mixed-media websites. Unlike print or television, online media permits communication to be layered and self-exploratory. One of the strengths of online communication channels is the ability to create multimedia stories that can combine video, animations, slideshows, written narrative, photography, and digital storytelling techniques. Deeper levels of a website can contain research details without cluttering the engaging and interactive content on the upper pages of navigation. The Archaeological Institute of America and *Archaeology Magazine*'s Interactive Dig website is a layered online experience that allows audiences to explore the processes of excavation along multiple pathways and in a range of different excavation contexts. Another example of rich format storytelling is the multimedia feature story, "The Thousand-Year Graveyard," produced by *Science* reporter Ann Gibbons. The story provided a behind-the-scenes look at an ancient Italian burial ground and used multimedia to highlight the site's significance, explain the archaeological methods used, and describe the lives of the people buried there.

Web 2.0 (user-generated content and social media platforms such as Facebook, Twitter, YouTube, and Instagram) is founded in the principles of interactivity, dialogue, and commentary. It has disrupted traditional communication hierarchies and democratized communication by encouraging users to develop their own curiosity about a subject and engage with it directly, either through comments, seeking out further online content, or uploading content of their own. The separation of archaeologists and the public in the generation and consumption of information has blurred. The consumers and producers of culture are now one and the same. Many archaeologists already leverage Web 2.0 channels to share their work, to promote or discuss interesting research, and to contribute to debates in the discipline. The self-editing philosophy of social media gives science communicators flexibility in their writing style, presentation, and use of multimedia to enrich their stories and posts. The strengths of Web 2.0 platforms are that they provide users (both science communicators and science consumers) with instant content updates, links to other resources, and access to people all over the world. Nonscientists have direct access to the latest scientific results, and scientists get feedback from practitioners regarding their ideas and their work. Archaeological information is accessible

24/7, and conversations between archaeologists and members of the public can happen in real time.

Online social networks also provide a variety of instant channels to share and cross promote research using other social media sites. The viral structure of social media gives communicators direct access to unexpected audiences. To leverage the full reach of Web 2.0 communication, science communicators seek out and connect with online opinion leaders and influencers. Social media "influencers" have established networks of hundreds of thousands, if not millions, of individuals online. The vast extent of their networks means these online influencers can attract quality discussion participants from diverse backgrounds to the science communicator's work simply by commenting on, sharing, or re-posting the story. Social media can therefore provide informal connections to people in other fields not readily accessible to archaeologists in the "real" world. In this way, an archaeologist may find novel insights or inspiration from a statistician, chemist, architect, linguist, or ecologist who is engaging with their work in the online environment.

Despite the unrivaled reach of the Internet, as a communication channel it can struggle to reach certain demographic groups, particularly the elderly, rural, and some lower-social economic groups. The sheer amount of available information can also make it difficult for audiences to recognize quality content. Another problem with online communication is that it is very difficult to control how content is picked up and subsequently interpreted and shared by other users. Social media in particular requires intensive and regular attention in order to maintain a successful online profile. It is also important to recognize that the existence of online scientific content does not necessarily equate to increased knowledge of that topic or to the use of such online resources in the absence of targeted outreach efforts.

Despite the general trend in online communication for concise, sometimes superficial, levels of information, other digital developments are opening up unprecedented access to scientific detail online. A good illustration of this in archaeology is advances in 3D scanning and geospatial technology. It is now possible to upload high-quality 3D reconstructions of artifacts, fossils, and even whole archaeological sites. The resolution of many of these scans allows people to explore archaeological materials in microscopic detail in a way never before possible outside of a lab. As 3D technology becomes more affordable, increasing proportions of people are able to afford 3D printers to print out models of 3D artifact scans in their own home. In 2017, English Heritage partnered with Google to use Google Street View and high-definition camera technology to create 360° walk-around images of heritage sites and artifacts for people to explore online. Many of these artifacts and sites have restricted physical access, and this technology makes them available to the public for the first time. The English Heritage-Google partnership is indicative of a trend in which archaeologists can expect to increasingly work alongside technology organizations in their communication activities in order to take advantage of digital skills, expertise, and technologies. The future of the digital communication of science will continue to reveal previously unrealized opportunities for communication and engagement using advances in the "Internet of things," virtual and augmented reality, real-time data, the semantic web, artificial intelligence, and big data. These new technologies hold great potential for the geographical, visual, and content-rich data of archaeology.

Over the last few decades, increasing public engagement in science and digital innovations has changed the way that science is both conducted and communicated. Online citizen science initiatives – projects that crowdsource participation from nonspecialist volunteers – have flourished. Archaeology was in many ways an early adopter of citizen science. Archaeological field schools, volunteer archaeology, site-stewardship programs, and community archaeology projects are all founded on public participation. However, online mass participation initiatives are only just beginning in archaeology. Online citizen science projects tend to be aimed at analyzing "big data." In archaeology, these huge datasets often result from the application of technologies, such as LiDAR (and other satellite imagery), geographic

information systems, and ancient DNA. "Big data" is increasingly common in archaeology as multivariate phenomena are used to understand complex processes such as human-environmental interactions, paleo-demography, and cultural complexity (Smith 2014). Archaeology can leverage citizen science in four main ways – mobile photography and scanning technologies (often in the field), site discovery and monitoring using satellite imagery databases, crowdsourcing of data input, and crowdfunding (Smith 2014). Citizen science is a powerful science communication tool because it encourages participation, dialogue, and understanding of science outside of academia by involving people in the research and data analysis process. It is also a practical solution for processing "big data" sets that might challenge the capacity of small research teams. However, these projects also bring new concerns for researchers: How should citizen scientists be acknowledged for their work? Do citizen scientists really learn anything substantive about the science in which they are involved?

A recent and well-known citizen science example in archaeology is the GlobalXplorer platform launched by Dr. Sarah Parcak at the University of Alabama in 2016. The GlobalXplorer project enlists people to identify and preserve global cultural heritage using high-resolution satellite imagery. Citizen scientists participate by searching for unrecorded archaeological sites and document destruction and looting at existing sites. Termed "space archaeology" in the mass media, Parcak's research programme has had an enduring component of public engagement and earned her the 2015 TED Prize. Other examples of archaeological citizen science projects, past and present, include the US site of Montpelier in Virginia; the medieval churches project in the UK; the Valley of the Khans project in Mongolia; and CITiZAN (Coastal and Intertidal Zone Archaeological Network) that monitors the threat to coastal and estuarine UK archaeological sites.

Public archaeology is another channel for direct and democratic communication between archaeologists and nonspecialists. Public archaeology, sometimes referred to as community archaeology, is a diverse field centered on public participation, service, and outreach in archaeological work through engagement and dialogue. It is specifically designed for, and substantially involves, local communities in research. This form of community-led participation and dialogue is most often found in historic, battlefield, postcolonial, indigenous, and urban archaeology projects that have clearly identifiable stakeholder communities. Rather than simply aiming to educate members of different publics about archaeology that is being conducted in proximity to them, public archaeology sets out to incorporate the values, ideas, and participation of public stakeholders into the project (Simpson and Williams 2008). The practice of public archaeology is redefining how archaeologists value and use community knowledge. Through active participation in archaeological projects, local and stakeholder communities can help shape research questions and contribute their own knowledge to the research exercise (Sabloff 2016). In community-led archaeology initiatives, trained archaeologists may take a consultant and advising role, while community groups take a more active role in directing the project. The Çatalhöyük Project in Turkey is an often-cited example of a successful community archaeology project, in which the interpretation of the site and site artifacts was discussed extensively with the local community (Bartu 2000; Bartu-Candan 2005).

One key aspect of public archaeology is engaging with contemporary issues in the communities within which archaeologists work. Archaeology can have political implications, whether implicit or explicit, which may touch on local, indigenous, or ancestral sensitivities. In these instances, communication through community partnership may be essential for the researcher to gain both understanding of the impact of their work on local people and the support and goodwill necessary to facilitate access to sites and materials. "Action archaeology" is part of public archaeology and reflects a growing recognition that archaeologists have responsibilities to the local and descendent communities with whom they work. Action archaeologists work for present-day communities, not just in proximity to them (Sabloff 2016).

Collaborative research between archaeologists and local communities is not new, but the importance and popularity of this combined research and communication approach have grown in recent years. Genuine dialogue and partnership between archaeologists and different publics can raise new research questions, enhance interpretations, generate local initiatives to protect and preserve sites from looting, or bring about social change through enriching group identities, reducing community divisions, or addressing historical biases (Little and Shackel 2007; Simpson and Williams 2008; Byrne 2012). Archaeologists hoping to use public or action archaeology to communicate and leverage these benefits must recognize that this approach requires a commitment to genuine partnership. Stakeholder groups should be involved throughout the project, from the design through to publication (Little and Shackel 2007). However, present-day research environments characterized by project-driven timeframes, rigid organizational structures, and cultures of accountability can be a serious challenge to engaged and democratic forms of science communication (Moussouri 2014). For an informative introduction to the different aspects of public archaeology, see the Public Archaeology entry in this volume and references therein.

Museums and exhibitions have a long-established reputation as centers for archaeological education and debate. They also play a social and democratizing role in society (Barker 2010). For centuries, museums have hosted public debates on scientific and archaeological discoveries and connected people to science through the objects housed in their collections. In the last few decades, museums have shifted their objectives from "teaching" their visitors, to understanding how visitors learn, make sense of the information, and form meaning. While objects remain a key part of museum exhibitions, the trend toward interactive, multimedia, and immersive museum displays demonstrates how museums intersect traditional and more democratic modes of engagement. Museum exhibits and experiences can use visual, textural, and multimedia communication to encourage visitors to actively explore and discover objects as a source of knowledge.

Long before the widespread uptake of the Internet, museums were developing as forums for informal, self-directed, and flexible communication and learning experiences. Exhibition spaces are increasingly designed to support interactivity and dialogue between visitors and museum staff and to challenge traditional knowledge hierarchies (Barker 2010). The Darwin Centre at the Natural History Museum London breaks down the physical barrier between its visitors and the curators, researchers, and objects. By giving visitor's access to the behind-the-scenes science and collections, the Darwin Centre supports learning and discovery through discussion, observation, and "hands-on" participation. One challenge for museum-based science communication is how to attract visitors who have neither the predisposition to visit museums nor a pre-existing interest in the subject. One approach to combat this is to leverage the strengths and allure of the arts and humanities by integrating painting, photography, poetry, and music into exhibitions on scientific topics. New formats for bringing scientific topics to new audiences include science cafes, science festivals, and even science comedy. Many of these new science communication formats have their roots in, and are often hosted at, museums and science centers.

For the second half of the last century, television was undoubtedly the most influential medium for cultivating public perceptions of archaeology to mass audiences (Holtorf 2007a). Although online digital platforms are increasingly encroaching on the supremacy of television as a communication channel, it remains a powerful tool for audiovisual storytelling. Archaeologists are often concerned at the potential trivialization of complex topics or the perpetuation of archaeological stereotypes in television programming. On the other hand, thoughtful archaeological programming increases public interest in the discipline and has helped to counteract sensational representations of archaeology (Holtorf 2007a). Television shows such as the United Kingdom's *Time Team* or *Britain AD* or the History Channel's *Digging for the Truth* can bridge the gulf between popular

culture and informative entertainment, while also conveying information about the process of archaeology (Clack and Brittain 2007). *Time Team*, which broadcast its final and 20th season in 2013, was the longest running archaeological series in the history of television and serves as a good indicator of archaeology's long-running popular appeal. Archaeological programming was present from the early days of television. In the 1950s, Mortimer Wheeler and Glyn Daniel were named British Television Personalities of the Year for their roles in the archaeological shows *Animal, Vegetable, Mineral* and *Buried Treasure*, programs which also guest-featured other well-known archaeologists including V. Gordon Childe.

Confusion about how to communicate, the amount of time to dedicate to it, and who the target audience is means archaeologists continue to rely on professional journalists to communicate the impact of their research through television, radio and print. Archaeologists concerned with journalistic appreciations of accuracy, detail, and uncertainty may fear media misrepresentation, but journalists can, and often do, produce balanced and informative archaeological stories with mass appeal despite using completely different rules of communication (Scherzler 2007). In the 1990s, an archaeological study of urban rubbish (Rathje and Murphy 1992) became a hot and thoughtfully reported media story because the authors and journalists were able to connect seemingly pointless trash to social, political, and environmental issues of the time. Over the last few decades, changes in both academic and journalistic professions have resulted in both sectors re-prioritizing their relationship to one another (Clack and Brittain 2007). Mass media journalism has begun to redefine and reassert its role in the online space after a difficult transition from "analogue" media. Archaeologists will continue to gain skills and confidence in using the Internet to communicate their research, but they will also need to develop their journalistic narrative and popular writing skills to maximize the reach of their research in the digital age.

Conclusion

Science communication is a vital bridge between researchers and different publics. Science communication in archaeology has the potential to positively impact political, ethical, and civic thinking and bring a range of benefits for the discipline. The ability of archaeology to create fascination, enthusiasm, and value about our collective past is an important contribution to building a rich and vibrant society. Archaeological methods and knowledge also result in scientific insights on long-term human trends. These trends can be relevant to contemporary issues faced by the world today. If archaeologists want these potential insights to inform and influence social, political, and economic decision-makers, then these insights need to be effectively communicated to government officials, policymakers, urban planners, business leaders, and a range of different publics. Although archaeologists are less frequently questioning if science communication is something they should do, they are still working out how best to do it. How, exactly, should we connect knowledge about how past humans lived in cities, coped with environmental changes, waged war, managed changing resources, established trade networks, or coped with new technologies, to parallel issues in the present?

To improve public perception and understanding of archaeology, archaeologists need to communicate engaging human stories. This requires embedding communication activities into core activities and evaluating the outcomes of different communication efforts. Archaeologists have a wealth of communication channels and approaches to achieve the varied goals of science communication in archaeology. Continuing developments in communication technology and theory will offer new opportunities to reach even wider audiences.

Successful science communicators know what they hope to achieve, with whom they want to communicate, and where they want to communicate it. They know that different audiences have vastly different cultural references, prior knowledge, and experiences. The shift

toward increasingly democratic and digital science communication should encourage archaeologists to reassess the different values placed on the past, how they share information, and the quality of their relationships with different publics. As scientists, archaeologists are as much knowledge communicators as knowledge creators. As communicators, archaeologists facilitate awareness of the existence, meanings, and worth of archaeological knowledge to support the publics' choice to engage with archaeology. The next challenge for science communication in archaeology is how to guarantee equal access to such knowledge for everyone with an interest in our collective human past and how this knowledge can effectively inform present-day issues in society. By working toward these goals, science communication in archaeology contributes to open, fair, free, and informed society.

Screening Methods in Archaeology

Marta Lorenzon
Centre of Excellence in Ancient Near Eastern Empires, Department of Cultures, University of Helsinki, Helsinki, Finland

Introduction

Screening methods are a relevant component of excavation methodology and are nowadays

included in most fieldwork experiences. Archaeological excavations are destructive actions; consequently it is of utmost importance to devise procedures that help to recover the higher amount of ecofacts and artifacts. The recovery of all possible finds is fundamental to avoid bias in the consequent analysis of the site.

Screening methods have been part of the archaeological discourse for the last 60 years and focus on the analysis of the removed sediments in order to recover smaller artifacts, usually missed during excavation. The methodology varies and can be divided into dry screening (or sieving) and wet screening, implemented by water.

Definition

Screening methods consist of analyzing the soil removed doing excavation through screen meshes of different sizes. This technique allows to recover artifacts and ecofacts, which are usually overlooked during the removal of the sediments due to their negligible size. Screening the soil directly impacts the amount of material that can be recovered and helps avoiding bias during sample collection (Balme and Paterson 2014: 262–268; Hester et al. 2016: 93–97; Renfrew and Bahn 2016: 177).

The screening is conducted through a mesh fixed on a rectangular screen box characterized by an open top. The screen box can be made of wood or metal and can be manufactured in different sizes depending on the amount of sediments to be processed (Fig. 1).

Screening Methods in Archaeology, Fig. 1 Screening box. (Image: M. Lorenzon)

The screening is often set up in the proximity of the digging area in order to facilitate the movement of soil from the actual excavation with buckets or wheelbarrows. Once brought to the screening area, the sediment is poured on top of the screen box, which is then shaken, manually or mechanically, to separate fine and coarse fractions as this latter usually includes the overlooked artifacts and ecofacts. The fine fraction of the sediments passes through the mesh, thus leaving the coarse fraction resting on top of it.

Hence, the choice of mesh size is particularly important and depends on the local geology of the site. For instance, a too fine mesh would not allow small pebbles to pass through and can be problematic in fluvial contexts, where sediments are mainly made of gravel.

Traditionally, four mesh sizes are used in the fields, 1/2 in., ¼ in., 1/8 in., and 1/16 in. (or 12.7 mm, 6.35 mm, 3.1–1.5 mm), but they are not exclusive and other sizes can be employed. In order to understand which mesh is required at any given site, a pilot sampling is often carried out, in which the sediments are initially screened through a fine mesh to determine the size required for that specific deposit (Connor 2007: 37–38; Reitz and Shackley 2012: 84).

Screening methods can be divided into two diverse techniques: dry and wet screening.

Dry screening is the sieving of sediments through a mesh and requires the soil to pass dry through the mesh. The mesh frame is suspended and can be positioned on legs or handheld. Sediments pass through the screens by shaking the mesh mechanically with a motor or simply manually when the mesh is operated by one or two people (Maschner and Chippindale 2005: 142–144).

On the other hand, wet screening consists of using water to help the sediments through the mesh. The running water is poured on top of the screen to help the soil positioned on top of the screen box to pass through it. Once the fine fraction passes through, artifacts and ecofacts left on the screen are retrieved and dried before being archived. While this method is efficient, it can also be problematic for sites located in an arid environment or sites that do not have easily access to water sources to

implement wet screening (Balme and Paterson 2014: 265, 293). Additionally, even though they share similar goals as identifying overlooked ecofacts, wet screening should not be confused with flotation, which follows a different methodology based on the density of the archaeobotanical remains (Renfrew and Bahn 2016: 244–250).

Both screening methods, dry and wet screening, can also be employed with a greater degree of accuracy in the laboratory environment during the post-excavation study period. Often soil samples from specific contexts (context samples) are packed and analyzed at a later date to answer specific research questions (see entry on "▶ Excavation Methods in Archaeology").

The choice between dry and wet screening is directly contingent to the type of sediment. For instance, wet silty-clayish soil can be particularly difficult to dry screen and often required water in order to break down clay bumps, separate the sediments from the artifacts, and move it through the screen (Balme and Paterson 2014: 262–264; Maschner and Chippindale 2005: 143). Some systems of screening involve the use of multiple screen boxes positioned on top of each other with different mesh sizes to increase the finesse of the analysis (Hester et al 2016: 93–97).

Finally, once the residue (i.e., artifacts and ecofacts) has been collected by dry or wet screening, it is sorted by separating bones, pottery fragments, shells, archaeobotanical remains, charcoals, and eventual other finds to proceed with specialist analysis (Balme and Paterson 2014: 262–264).

Key Issues/Current Debates/Future Directions/Examples

The choice of appropriate screening techniques is of essential importance in order not to negatively affect the recovery of finds (Hageman and Goldstein 2009; Reitz and Shackley 2012: 83; Shaffer 1992; Shaffer and Sanchez 1994). This major issue relies on three cardinal points: (1) there is not a "one and only" screening method that can be applied to every site; (2) screening technique should be consistent within the same excavation; and (3) the methodology selected should offer to all finds the same likelihood to be recovered (Balme and Paterson 2014: 262–264; Reitz and Shackley 2012: 83–84; Watson 1972).

Thus, the analysis of the site matrix is essential to determine which screening techniques should be implemented at each site to recover all the cultural and environmental finds (Hageman and Goldstein 2009; Reitz and Shackley 2012: 85). Ingbar's investigation (1985) tests the efficiency of diverse screening methods and indicates dry screening as more effective than wet screening while dealing with sandy deposits since it allows for a more efficient recovery of finds. On the other hand, numerous studies indicate that clayish soils often require water to uncover finds, and recovery percentages are negatively affected by dry sieving (Burke et al. 2009: 170; Pearsall 2000: 18–22; Reitz and Shackley 2012: 86).

In the best-case scenario, different techniques should be tested and implemented based on the type of sediments (e.g., prevalence of clayish, loamy, or sandy soil) as soil types clearly influence the choice of recovery method. Furthermore, they have a direct impact on the density of finds uncovered and their successive interpretation.

Likewise, the selection of mesh size deeply affects the recovery of artifacts as the choice of the wrong mesh may alter quantitatively the amount of microfauna recovered (Orton 2000: 164–165). Sapir-Hen et al. (2017) illustrate this key issue through a well-designed case study at Dor, presenting the impact on the archaeologists' interpretation when the percentage of macrofauna vs microfauna highly varies based on distinct mesh sizes and techniques. In this case the fluctuation in finds' density results may be attributed equally to different techniques, diverse mesh size, or altered patterns of human behavior present at the site. Therefore, this ambiguity should be discussed in the publication and acknowledged as a relevant factor affecting the archaeologist interpretation (Sapir-Hen et al. 2017).

Additionally, while the main aim of selecting the right screening method or mesh size is to drastically reduce the prejudice on collecting artifacts and ecofacts, there are still biases to be considered in the subsequent analysis and interpretation established by the sampling strategy

carried out during excavation (Pearsall 2000: 112–116; Reitz and Shackley 2012: 88–91; Shaffer 1992). If not all the excavated deposits undergo screening, soil sampling – and the rationale behind it – becomes essential to understand contexts, occupational levels, and findings. Sampling rationale involves multiple factors such as prior knowledge of the area, representativeness, and accessibility (Hester et al. 2016: 25–39; Pearsall 2000: 69–71). These factors have a direct effect on the method's reliability and accuracy and need also to be acknowledged when interpreting the finds.

Consequently, the methodology used and the eventual sampling rationale should be clearly stated in the final report to recognize and consider possible prejudices on the interpretation of the excavation materials.

Another noteworthy issue connected to screening methods deals with the treatment of fragile materials as these can be negatively affected by recovery techniques. For instance, careless screening can easily damage fragile ecofacts and artifacts as shells and bones can be broken when forcefully hit by stones during sieving or painted artifacts (e.g., plaster, pottery) can be damaged by water during wet screening. Thus, screening should be carefully implemented with sediments that presents an abundance of these types of cultural and environmental finds (Balme and Paterson 2014: 326; Hester et al. 2016: 93; Reitz and Shackley 2012: 85).

A secondary problem in outlining screening methods is to clarify the difference between wet screening (or water screening) and floatation as the two methods fulfill different purposes (Maschner and Chippindale 2005: 779–781; Pearsall 2000: 15–29). Flotation is not usually performed on the integral excavation, but only on selected samples to help recovering archaeobotanical finds (seeds, plant remains, pieces of wood charcoal) (Renfrew and Bahn 2016: 244–250; Pearsall 2000: 15–29). It consists of immerging a soil sample contained in a mesh, or catch sieve, inside a body of water, which is then shaken to separate light-density materials. Various typologies of floating devices are currently used in archaeology (Wagner 1988; Pearsall 2000: 15–20).

Finally, screening is a time-consuming technique, and excavation expediency often requires to work out a balance between methodological accuracy and efficiency (Burke et al. 2009: 167; Reitz and Shackley 2012: 89). For instance, large-scale excavations need to consider that all the excavated contexts should receive the same level of screening, and this latter task often requires multiple people assigned to it. Alternatively, a sample strategy can be implemented, but it requires to be well designed in advance and stating clearly the screening rationale and its impact on post-excavation analysis and publication of the results (Hageman and Goldstein 2009; Ingbar 1985; Sapir-Hen et al. 2017; Quitmyer 2004).

Sea-Level Changes and Coastal Peopling in Southernmost Pacific South America: Marine Hunters from Patagonia

Manuel San Román
Centro de Estudios del Hombre Austral, Instituto de la Patagonia, Universidad de Magallanes, Punta Arenas, Chile

Introduction

Patagonia is the southernmost tip of South America and in general terms is constituted by two sharply contrasting territories. The first corresponds with the eastern slopes of the Andes Cordillera and is characterized by plains and plateaus, a semidesert climate and steppe and shrub vegetation, extending to the Atlantic coast. This part was occupied by land hunter-gatherers from the late Pleistocene to the early twentieth century. The second belt characterized by a vast archipelago occupies the western slope of the Andes from the Chacao Channel (46° south latitude) to Cape Horn (56° south latitude). In this region, ethnographic and historical information describes three ethnic groups, which include from north to south: Chonos, between Chiloé Island and Tres Montes peninsula; Alacalufes or Kawésqar, from the Gulf of Penas to Brecknock channel; and Yamana or Yagan, who lived from Brecknock to Cape Horn (Fig. 1). The three groups shared livelihoods based on hunting, gathering, and fishing of marine species and the use of navigation technologies basically canoes built with sewn planks (Chonos) or bark (Alacalufes and Yamana) (Bird 1946; Cooper 1946; Gusinde 1986[1937], 1991 [1974]; Emperaire 2002 [1963]; Lothrop 2002 [1928]). From a linguistic point of view, these ethnic groups shared a common trunk that diverged about five millennia ago (Viegas Barros 2005). Archaeological data establishes that the oldest sites of marine hunters for the southern cone of South America are concentrated in the south and reach 6,500 years BP. This period overlaps with the pick of the worldwide mid-Holocene marine transgression and with a general temperature and moisture increase associated with a major outbreak of forest cover. The origin of these adaptations is still under discussion, as well as the colonization of this vast coastal region.

Following, the main geographical features of the archipelagic region, the implications of different geological processes in sea-level changes and coastal evolution, and the main features of early Patagonian marine hunters are considered. Then, after outlining the history of archaeological research in these topics, we will present a brief summary of key issues under discussion for this subject, considering the origins of these adaptations and cultural evolution of marine hunter settlement in the southern cone of South America.

Sea-Level Changes and Coastal Peopling in Southernmost Pacific South America: Marine Hunters from Patagonia, Fig. 1 Localization map with main marine hunter archaeological sites from Patagonia

Definition

Environmental Characteristics of the Southernmost South American Pacific Coast

An intricate archipelago develops south of Chacao Channel (46°South Latitude) up to Cape Horn (56° South Latitude); it describes an arc approximately 1,800 km long, with an average width of 120 km from the Pacific coast to the foothills of the Andes Cordillera. The Patagonian archipelago has an estimated length of over 19,000 km of coastline (Bird 1988). The main factor that shaped the topography of this region corresponds to the erosive action of Quaternary glaciations that carved an intricate system of valleys, later flooded during the Holocene rise of

global sea level. The central zone between the Gulf of Corcovado (43°50′ South Latitude) and Última Esperanza Sea (51°50′ South Latitude) presents two continental ice fields and major mountain ranges that significantly limit pathways between the Pacific and Atlantic basins. In addition, the circulation is severely restricted due to steep coastlines and the presence of many front glaciers that divide the continental shore.

Dominated by a humid climate, with rainfall averaging 5,000 mm per year in the western band, this region is dominated by dense forest and peat bogs. The marine fauna is rich and varied. The most abundant marine mammals are pinnipeds (*Arctocephalus australis*, fur seal, and *Otaria flavescens*, sea lion), and whales and dolphins are also frequently recorded. Terrestrial fauna is much more limited and includes two species of deer (*Hippocamelus Bisulcus* and *Pudu puda*) and a camelid (*Lama guanicoe*), although the latter is recorded only in the extreme northeast and southeast of the area. Edible vegetables are rare and had a minor role in the human diet.

Coastline Evolution

Since the late Pleistocene period, much of the extensive coastline and mountains were covered by great ice masses, and during the Late Glacial Maximum (LGM), the sea level was about 120 m below the current level. In this period, the Pacific coast was located further to the west of its current position, and large basins and fjords were occupied by ice or proglacial lakes. Hereafter, with glacier retreat and gradual rise in sea level starts a process of maritization, a quick shoreline modification which along the Holocene will shape the archipelago as we know it today. For example, toward 8,000 years BP, Tierra del Fuego Island is separated by the opening of the Strait of Magellan and the same applies to Navarino Island with the formation of the Beagle Channel, in the far south. This process of sea-level rise reaches its peak some 6,000 years ago, and sea reached current levels around 500 years ago. As for the specific case of the central part of the Strait of Magellan, between continental Patagonia and Tierra del Fuego, the marine transgression reached an elevation of about 3.5 masl near 6,000 years BP. Because of isostatic rebound, marine terraces have decreasing elevations from west to east between 10 and 3 masl, as the western areas covered by ice during the last glacial advance have increased isostatic rise, compared to the eastern portion that was ice-free during this period (Porter et al. 1984; McCulloch et al. 2005).

Changes in sea level combined with tectonic and isostatic processes acted differentially in coastal evolution of Patagonian archipelago shorelines. From the Gulf of Penas northward starts tectonic plate contact which stretches for thousands of miles along the Pacific coast of South America, between the Nazca and South American plates. This conjunction gives origin to an important tectonic activity associated with plate subduction, resulting in an intense process of sinking and/or uprising, periodically triggering large-scale seismic activity that often is associated with the generation of tsunamis. There are few measurements for central and northern Patagonian archipelago coastal evolution. However, it has been established that during the mega-earthquake of Valdivia (1960, 9.5 MW), a band between the Chacao Channel zone and Gulf of Penas would have sunk up to 2.4 m while some islands located west of the area rose to 5.7 masl (Plafker and Savage 1970). South of the Gulf of Penas, tectonic activity is less intense and is controlled by other factors. For example, in the east-central part of the Strait of Magellan, Holocene marine terraces of different ages are observed, while in the western portion, these terraces are absent. This is due to tectonic activity associated with a fault system that would have caused vertical movements of the crust in this specific area (McCulloch et al. 2005; Cisternas and Vera 2008).

Early Marine Hunters from Patagonia, Archaeological Assemblages

The available information is concentrated in the southern and northern ends of the archipelago, because archaeological research has focused in these areas. At the moment, the vast central archipelagic zone record is limited to late Holocene sites.

In the southern zone, we find the oldest records of marine hunter-gatherers with navigation media,

at sites located within the Otway Sea-Strait of Magellan and Beagle Channel-Navarino Island localities. The archaeological sites have been dated between 6,500 and 5,000 years BP and are located at altitudes between 7 and 17 m, usually associated with ancient Middle Holocene marine land forms. The most important traits of material culture are present on bone tools as detachable harpoon points with one or two barbs and cruciform base, multi-denticulate harpoons, chisels on pinniped ulnas, cruciform base stemmed wedges on whalebone, and ornament artifacts as pendants on drilled or grooved pinniped incisors. Lithic artifacts are characterized by subtriangular projectile points, knives, other instruments with elongated edges, and fishing-line weights with grooves and/or side notches. We highlight the use of a volcanic rock, a green obsidian whose source is unknown at present and that is recorded in the vast majority of archaeological sites in the southern region. The faunal assemblages are dominated by fur seals, birds, and fish, and shell middens are described as characteristic features. The presence of sites on islands confirms the existence of well-developed navigation technologies. This assemblage has been defined as a cultural tradition called *Englefield* (Fig. 2).

In the same area, between 5,000 and 3,000 years BP, cultural evidence showing technological changes is recorded in archaeological sites including the presence of large lithic lanceolate projectile points, in concordance with less frequent bone harpoon points and the virtual abandonment of green obsidian use (Fig. 3). The quantifications of exploited fauna indicate an increase in guanaco hunting. The sites are located between 4 and 8 masl, associated with sea-level regression and coastline retraction during this period.

The northern end of the archipelago earliest archaeological records are somewhat less antique, spanning from 5,500 to 4,000 years BP, and include sites emplaced between Reloncaví Sea and Gulf of Corcovado (Guayaneco Archipelago). Artifact assemblages are characterized by lanceolate projectile points carved bifacially and fishing-line weights with side notches, among other tools (Fig. 4). Exploited fauna consisted mainly of sea lions, fish, and seabirds, with important shell midden accumulations. The location of sites varies between 0 and 10 m, elevation differences related to local variations in sinking and/or uplifting tectonic processes in this area. Interaction between groups in this area is attested by the presence of obsidian artifacts from a rock source located at Chaitén Volcano.

Historical Background

Research in the pacific southern coast began with ethnological work in the far south, associated with the description of the last Yamana (Gusinde 1986[1937]; Lothrop 2002 [1928]; Martial et al. 2007 [1888]) and Alacaluf ethnic groups (Gusinde 1991 [1974]; Emperaire 2002 [1963]). Nevertheless, the first archaeological excavations go back to the 1870s in Isabel Island, in the central part of the Strait of Magellan (Borrero et al. n.d.). Later, ethnological work led to initial questioning of the antiquity of marine hunter population, and estimates based on observations of shell deposit accumulation rates, elevation of sites above sea level, and isostatic lifting rates calculated for that epoch were made in the decades of 1920 and 1930 (Bird 1946; Lothrop 2002 [1928]). They reached pioneer dates with a maximum around 2,500–5,000 years BP. In this period, Junius Bird carried out test pit excavations in different areas of the archipelago, developing an initial cultural outline and periodification for the southernmost area, but details were never published.

Systematic archaeological excavations would begin in the southern end between the 1950s and 1960s, conducted by the French ethnologist and prehistorian Joseph Emperaire within the Otway Sea. His excavations at Englefield, located on an ancient marine terrace on the homonymous island, led to the first characterization of an early marine hunter group in Patagonia. Another relevant site excavated by Emperaire, called Ponsonby, is located along the Fitz-Roy Channel. The locus offered the first description of an assemblage dominated by lanceolate projectile points and

Sea-Level Changes and Coastal Peopling in Southernmost Pacific South America: Marine Hunters from Patagonia, Fig. 2 Lithic and bone artifact assemblage from early marine hunters, Englefield Tradition: (**a**) harpoon points with one and two barbs and cruciform base, (**b**) chisels made on pinniped ulnas, (**c**) pendants on pinniped perforated teeth, (**d**) green obsidian bifacial-knife instruments, (**e**) fishing-line weights and (**f**) subtriangular projectile points (green obsidian)

other bone and lithic artifacts that markedly differed from those recorded in Englefield. The site survey was interrupted by the tragic death of Emperaire who died buried by sediments during his excavation work.

During the first half of the 1970s, the work of Chilean archaeologist Omar Ortiz-Troncoso allowed discovering two new sites on the Strait of Magellan shoreline, with a similar assemblage to those described in Englefield Island. Excavations at sites Punta Santa Ana and Bahia Buena confirmed the technological and economic relationship, integrating them as a cultural tradition with a 1,500-year phase. The dates obtained in the

Sea-Level Changes and Coastal Peopling in Southernmost Pacific South America: Marine Hunters from Patagonia, Fig. 3 (**a**) Large lanceolate lithic projectile points and (**b**) harpoon point from sites in Southernmost Patagonia dated between 5,000 and 3,000 years BP

Sea-Level Changes and Coastal Peopling in Southernmost Pacific South America: Marine Hunters from Patagonia, Fig. 4 Lithic artifact instruments from early marine hunters of northern Patagonian archipelago, spanning between 5,500 and 4,000 years BP: (**a**) lanceolate lithic projectile points and (**b**) fishing-line weights

Strait of Magellan were located in a range between 6,400 and 5,200 years BP.

At the southernmost end of the archipelago, specifically on the north shore of Beagle Channel, archaeological research started in the mid-1970s led by Argentinean archaeologists Luis Abel Orquera and Ernesto Piana. Their research developed and characterized an archaeological sequence for the settlement of marine hunters in this zone. Excavations at Tunel 1, Imiwaia, and Lancha Packewaia sites, located on the southern coast of Tierra del Fuego Island, allowed recording a peopling sequence spanning the last 7,000 years BP. The earliest evidences, with dates around 7,850 years BP in the layer S of Imiwaia and 6,800 years in the first component of Tunel, were interpreted as brief occupations generated by terrestrial hunters and with no ties to later assemblages of marine adaptation groups. Following the stratigraphic sequence, further above in the second component of the Tunel I site and Imiwaia are dated between 6,400 and 4,300 years BP, the sites render another assemblage. The material cultural verifies an association with the bone and lithic industry described in Englefield, highlighting the same detachable harpoon points with cruciform base, multi-denticulate harpoons, chisels on pinniped ulna, and cetacean bone wedges. Outstanding decoration is invested on bone tools, and various ornament artifacts, including pendants on pinniped incisors, are recorded. A peculiarity of Beagle Channel assemblages is related to morphological variations in harpoon points with cruciform base. The stone tools are similar, stressing the rare but regular record of green obsidian artifacts that attest interaction between early human groups settled in the Beagle Channel and the Strait of Magellan-Otway Sea. In relation to Lancha Packewaia site, there are two stratigraphic assemblages, an old component dated near 4,200 years BP and another recent group of artifacts dated after 1,600 years BP. The former component is noted because of its striking similarities with Ponsonby site, dominated by big lanceolate lithic projectile points and fauna records that attest an important role of guanacos in the diet (Orquera and Piana 1999, 2009; Orquera et al. 2012).

During the 1980s, the French Archaeological Missions in southern Patagonian archipelagos are restarted by Dominique Legoupil. The excavation of Bahia Colorada site, located on a high terrace in the eastern coast of Englefield Island, allowed her to characterize in great detail this assemblage, defined thereon as Englefield cultural tradition. Another landmark was the reassessment of the Ponsonby site, describing an occupational sequence of seven millennia. The earlier component has a chronology in the order of 7,000 years BP, but few materials, of little diagnostic value, were found in association with faunal remains of guanaco. This archaeological level was interpreted as the result of ephemeral terrestrial hunter campsite activities at a time prior to the opening of the Fitz-Roy Channel and Riesco Island. Further up, the main component of Ponsonby site is associated with a rich lithic industry characterized by large lanceolate projectile points and the predominance of guanaco consumption, with dates between 5,000 and 3,000 years BP. This assemblage shows remarkable similarities with the Lancha Packewaia site oldest component and corresponds to a second cultural tradition for southern Patagonian marine hunters.

Research in the northern archipelago started later, noting at the beginning of the 1970s the publication of Chilean archaeologists Cristian Diaz and Marcelo Garretón informing about the systematic excavation of Conchal Gamboa site, a big shell midden located on the eastern coast of Chiloé Island. This work is the first description of marine hunter-gatherers context. From the collection, we can note the lithic lanceolate projectile points and some decorative elements made on bones and shells (Diaz and Garretón 1972–73). This site was not radiocarbon dated and remained an isolated reference to early canoe groups in the area until the late1980s, when researcher Charles Porter discovered and characterized the site Guaitecas 10, located immediately south of the Gulf of Corcovado and dated around 5,000 years BP. Porter's work was pioneer in highlighting the impact of tectonic subsidence phenomena and its relevance in differential preservation of archaeological

evidence in the northern Patagonian area (Porter 1993). After the 1990s, new evidence of early settlement of hunter-gatherers resulted from the excavations conducted by archaeologists Carlos Ocampo, Pilar Rivas, and Eugenio Aspillaga at Puente Quilo site, north of Chiloé Island (Ocampo and Rivas 2004), and Nelson Gaete rescue excavation in Piedra Azul site, recovered on the shore of Reloncaví Sea (Gaete et al. 2004). These sites correspond to shell middens with stratigraphic sequences of occupation ranging from 5,500 years BP until at least the first millennium AD. In general, the assemblages are associated with early industry markers: big lanceolate lithic projectile points carved bifacially, fishing-line weights, and some contexts also include multi-denticulate bone harpoons.

Key Issues and Current Debates

Origin of Maritime Adaptations for the Southern Pacific Coast of South America

One of the main questions of the prehistory of the Patagonian archipelago is the origin of marine adaptations. The explanation of the peopling process is held by two main hypotheses. The first supports a local origin from pedestrian hunter groups that would have developed specialized technologies for the exploitation of marine resources (harpoons, fishing techniques) and a transport media – canoe – which would have allowed colonizing this region. Two likely areas for the development of this process have been indicated: the northern archipelago, which includes the Reloncaví Sea and Chiloé Island (Ocampo and Rivas 2004), associated with a lanceolate projectile point tradition and the southern archipelago, near the Strait of Magellan and/or Beagle Channel, linked to the development of the Englefield cultural tradition (Legoupil and Fontugne 1997; Orquera 2005; Orquera and Piana 2009).

The second hypothesis bases its explication on migration of hunter-gatherer groups equipped with water transport, canoeists which would have arrived in the archipelagic region from the north, along a Pacific coastal route.

Among arguments pro or against the hypothesis of the origins of these prehistoric human adaptations, we must note that older ages for sites in the southern end suggest a local source. But in return, the early records show a high degree of technological specialization (harpoons, deep-sea fishing, navigation aids). A reasonable expectative that could support local origin as explanation of this maritime adaptations would be to find older evidences and cultural traits of evolving local development describing different stages of experimentation and adaptation to marine environments. Nevertheless, this evidence has not been recorded for the area. Furthermore, the second hypothesis of migration of populations from the Pacific coast is not supported by existing data, as the northern coast sites from Chacao Channel upward possess ages considerably lower than early sites from the southern end.

A core issue to verify any of the alternatives for the origins of maritime settlement in Patagonia lies on the scarcity of coastal sites that predate the Holocene marine transgression. This fact could be explained because the shorelines would have been submerged and/or eroded during this period of marine transgression. The only sites currently registered that correspond are Ponsonby – initial occupation – in Fitz-Roy Channel and Tunnel I first component and Imiwaia I ancient occupation in southern Tierra del Fuego. Nevertheless, these assemblages have been interpreted as a result of the occupation of terrestrial hunters (Legoupil 2003; Orquera et al. 2012).

Cultural Trajectories in Maritime Settlement

As for the cultural evolution of coastal settlement, we can state that in the northern archipelago, in Chiloé Island and Reloncaví Sea, researchers describe continuity in technological traditions and subsistence during the hunter-gatherer occupation periods, noting that during the last millennium, pottery is recorded in association to the arrival of horticultural populations of Huilliche-Mapuche ancestry.

South of Gulf of Corcovado prehistoric groups keep a hunter-gatherer lifestyle unto historic times. However, there are different interpretations

as to whether or not there was cultural continuity along the sequence, particularly in the case of the southern end. For Piana and Orquera (2007), the archaeological sequence shows a remarkable continuity, homogeneity, and stability over time, considering the subsistence elements, lithic and bone tools, and lifestyle in general. Other researchers argue that there would be a major change from the appearance of assemblages related with big lanceolate projectile points, remarking these sites as constituting a different cultural tradition, possibly related to assemblages described in the northern part of the archipelago (Morello et al. 2002; Ocampo and Rivas 2004; Schidlowsky 2004). Evidence supporting the identification of different traditions is based on both the appearance of new stone-tool designs, involving operational chains and methods of fabrication, as well as the abandonment of green obsidian lithic raw material use, particularly in the Strait of Magellan-Otway Sea area, where the source would be located. Among the hypotheses that would account for the emergence of a new cultural tradition, the possibility of migration of marine hunter groups from the northern area is raised. While a common hunter-gatherer marine lifestyle is a constant for 6,500 years, it is clear that there are changes in technology and wildlife resource exploitation. Current discussions are focused on the processes which could explain the changes perceived in the archaeological record through time. The argument that supports the notion of continuity tends to interpret these changes in technology and use of raw materials as innovation or diffusion involving no fundamental cultural change (Orquera et al. 2011). The counter arguments indicate that changes in technology and in the use and knowledge of certain raw materials involve cultural aspects that must be transmitted from generation to generation and characterize a distinct cultural tradition, therefore involving an essential cultural shift (Figs. 2, 3, 4, and 5).

International Perspectives

The study of the peopling of the Patagonian archipelago has a vast importance in the research on processes of colonization and effective occupation of the marginal end frontiers of the Americas. This region forms a distinctly marine environment, both because of its predominant wildlife resources and its geographical setting, which makes it necessary the use of navigation media to travel around this intricate system of fjords, channels, and islands. The origins of maritime adaptation in Patagonia face us to a global problem related to the challenge of identifying archaeological evidence previous to the coastal marine transgressive phenomena (Massone et al. 2013). Researches in other areas of the Americas have determined coastal occupation records of at least 10,000 years BP. Some of these sites are located in the coastal desert of southern Perú and northern Chile. Furthermore, the presence of hunter-gatherer populations in late Pleistocene continental areas adjacent to the archipelago makes it plausible to propose a much older appearance of marine adaptations in Patagonia than those reported to date. The search for information that would give support to this idea confronts us with a crucial methodological and theoretical duel, that of designing search strategies that allow exploring conditions that might have preserved this type of evidence.

Future Directions

The current state of knowledge about the prehistory of Patagonian archipelago is restricted to areas located inland, along the continental coast and/or located on islands nearby narrow channels that were covered by glaciers during the LGM. It is a paradox that until now no research efforts have been done to incorporate the extreme western pacific coastline. Free of ice since the late Pleistocene, this area currently concentrates the greatest number and diversity of fauna of the region, something that could not pass unnoticed by hunter-gatherer populations. These characteristics determine the importance of incorporating the area in future research efforts.

In addition to expanding research areas, the incorporation of survey designs based on geomorphological studies to help guide the search for areas that could preserve ancient coastlines from times preceding the Holocene marine transgression should be achieved. In this sense, it is relevant to explore areas where tectonic phenomena and isostatic uplift of the land crust could contribute to the preservation of this type of evidence. This line of work can substantially contribute new evidence to the debate about the antiquity of coastal settlement and mechanisms – being migration or local development and adaptation – that have operated in the colonization of the American border.

Second Modernity and the Second Phase of European Colonialism

Daniel Rhodes
National Trust for Scotland, Edinburgh, UK

Introduction

The impact of European Colonialism upon world cultures has been, and continues to be, undeniably profound. More and more in contemporary archaeology (and heritage studies) this impact is being recognized in the way we formulate our perception of the past. Whether our gaze be cast upon pre-colonial societies or colonial and post-colonial heritages, it is all unavoidably (it can be argued) viewed through the lens of the European colonial influence.

Definition

The term *Second Modernity* is a theory first developed by philosopher Enrique Dussel in relation to

the historic period between the seventeenth and the second half of the twentieth century. It refers to the idea that people who live under colonial rule are subject not only to Western economic and political forces but are also influenced in the way they see and think of themselves (and others) based upon a change in mindset brought about by Western influence and control. The *Second Phase of European Colonialism* is the period of world history when global mercantile activities led to the development of European colonies, most notably by Britain, Holland, France, and later Germany, and largely focused on Africa and India from the seventeenth century until colonial states began to acquire independence in the second half of the twentieth century. This is sometimes referred to as *New Imperialism* and follows the earlier period of European Colonialism (or *First Modernity*) that saw Spanish and Portuguese exploitation in the Americas. The two are inseparably linked in the way that the global historical activity that occurred during the Second Phase of European Colonialism resulted in the development of subaltern non-colonialist social theory such as Second Modernity.

Historical Background

Developed out of postcolonial studies and specifically Latin American Social Theory, the idea of Second Modernity was a response to Marx's lack of analyses of class struggle in Latin America and his apparent skepticism in the development of the bourgeoisie in non-European societies. The bourgeoisie were central to Marx's theory of social change, or "Universal History," as it was the bourgeoisie who represented the first revolutionary class in history and who (through maintaining the ability to control and revolutionize the means of material production) were able for the first time to actively influence and change social relations. This, however, he did not apply to feudal societies. It was the development of international markets through the tool of colonialism that Marx saw as the necessary stage through which a previously feudal society must pass before the creation of the revolutionary bourgeoisie. His assessment was, however, from a purely European perspective and the lack of investigation into the development of capitalism outside that of the European model (i.e., where colonial control implanted European structures into non-European geographies). As Castro-Gómez (2008: 262) observes, "Latin America was, it seemed to Marx, a grouping of semi-feudal societies governed by large landowners that wielded their despotic power without any organized structure." Colonialism is then, for Marx, a tool of capitalism and responsible for the overthrow of feudal societies in the march toward revolution. Colonialism in effect "delivers" capitalism and, by association, the revolutionary bourgeoisie. He did not see, as others have subsequently done, that colonialism is more than an economic or political phenomenon. And it was the study of this more expansive and socially pervasive impact of colonialism that lead to the growth of late twentieth-century subaltern social theories from former European colonies of which Second Modernity and the writing of Enrique Dussel was one.

Dussel argues that European modernity was founded on materiality that had been specifically created after Spain's sixteenth-century territorial expansion (Castro-Gómez 2008: 272). He goes on to argue for the historical existence of two modernities. This first began in the sixteenth century when the Christian Renaissance spread globally via Spain's colonial domination of the Americas, and the second was the colonial expansion into Africa and Asia by Britain, Holland, France, and later Germany.

Enrique Dussel was born in 1934 in La Paz, Mendoza, Argentina, and is best known as one of the founders of the movement known as the Philosophy of Liberation. His writing aims to dismantle the nature of European thinking by critiquing the Eurocentrism of modern philosophy and characterizes the dominant model of philosophy as one of European conquest over the rest of the world (in this way mirroring Said's ideas of "Europe" and the "Other" (Said 1978) and Wallersteins' (1980) world-system with its "Core" and "Periphery." In doing this Dussel (1995: 148–49) aimed to liberate non-European

social discourse from the "Eurocentric myth of modernity":

> Modernity is not a phenomenon that can be predicated on a Europe considered as if it were an independent system, but only about Europe if it is conceived as a centre. This simple hypothesis completely transforms the concept of modernity, its origin, development, and contemporary crisis, and consequently it also transforms the content of late and post-modernity. In addition, I would like to introduce another idea that qualifies the former: Europe's centrality within the world-system is not the result of an internal superiority accumulated during the European Middle Ages about and against other cultures. It is instead a basic effect of the discovery, conquest, colonization, and integration (submission) of Ameri-india. This simple fact gave Europe the comparative and determinant advantage over the Ottoman-Islamic world, India and China. Modernity is the result of these events, not their cause. Therefore, it is the administration of that centrality within the world-system that would allow Europe to become something like "the reflexive consciousness" (the modern philosophy) of world history. . .Even capitalism is the result and not the cause of this conjunction between European expansion around the world and the centralization of the world-system.

As a result, any study of world heritages should recognize non-European cultures for the role they have in the reflective dominance of European cultural narratives.

Another important figure in the development of the idea of Second Modernity and its intrinsic tie to colonialism is Walter Mignolo. Mignolo developed a critique of Wallerstein's world-systems theory based upon Dussel's ideas of the (non-bourgeois) Hispanic world, arguing that "World-systems analyses is indeed a critique of Eurocentrism, but a Eurocentric critique of Eurocentrism" (Mignolo 2000: 314).

World-systems analyses are based upon a neo-Marxist model of economic history formulated primarily by Wallerstein in the 1970s and 1980s (Wallerstein 1980, 2005). It attempts to explain economic globalization, or supranational economic activity, through the concept of inequitable interrelation between national economic units. The model's primary supposition is that the economies of "the developing world" are in every way effected by (and should therefore be analyzed in terms of their relation to) the economies of the wider world, a world which is dominated by the USA, Japan, and Europe. Like Marx, Wallerstein argues that the modern capitalist world-system originated in Europe in the sixteenth century via the economic transformation from feudal organization to capitalist (Wallerstein 1980: 2005):

> . . .our original primary purpose was to show that most production within the capitalist world-economy that placed items for consumption on the market was the result of a long chain that did in fact cross frontiers, and that this had been so throughout the entire history of the capitalist world-economy from the long sixteenth-century to today (Wallerstein 2005).

Mignolo bases his criticism of Wallerstein's world-system on the opinion that the theory is simply another example of Western ideas being presented to non-European peoples as *the* model for critical analyses. In his explanation Mignolo quotes Darcy Ribeiro:

> In the same way that Europe carried a variety of techniques and inventions to the people included in its network of domination. . .*it also introduced to them its equipment of concepts*, *preconcepts*, *and idiosyncrasy that referred at the same time to Europe itself and to the colonial people*. The colonial people, deprived of their riches and of the fruit of their labor under colonial regimes, suffered, furthermore, the degradation of assuming as their proper image that was no more than the reflection of the European vision of the world. . .. (Ribeiro 1968: 63 in Mignolo 2000: 13).

In looking at cultural identity and modernity in Latin America, the Peruvian sociologist Aníbal Quijano also put forward the argument during the 1990s that colonial power cannot be reduced to economic, political, and military domination of the world by Europe, but that it also supports and spreads globally European models of the formation of knowledge in modernity (Castro-Gomez 2008: 280). This is what Gómez calls the "coloniality of power" and sees the action of colonization as attempting to replace Indigenous forms of knowledge with those more appropriate to the underlying aims of the controlling Western regime.

This relationship between capitalism, colonialism, and the control of the formation of knowledge can, arguably, be seen in the histories of the expansion of mercantilism across national

frontiers throughout the world in the later European historic period (closely linked to Britain's industrial revolution and France's bourgeois revolution). The period categorized the Second Phase of European Colonialism.

Portugal (in alliance with Spain) was the world's major colonial power during the first phase of European Colonialism in the sixteenth century. This was to begin to diminish in the seventeenth century, a fall which was precipitated by the defeat of the Spanish Armada in 1588. By 1600, the formerly dominant Portuguese maritime establishment was in no state to counter the dual mercantile threat of the new royally chartered English East India Company and, in 1602, the Vereenigde Oost-Indische Comagnie (Dutch East India Company). The East India Company (EIC) was first established in 1600 as a joint-stock association of English merchants under the title of "The Governor and Company of Merchants of London Trading into the East Indies," the "Indies" being defined as the lands lying between the Cape of Good Hope and the Straits of Magellan. The aim in trading in the Indian Ocean for both the English and the Dutch was not Africa or India primarily, but Indonesia or the Spice Islands beyond. During its first 10 years the EIC sent 17 ships to Asia, in contrast to the VOC's 134. The result being that the Dutch were able to establish trade settlements at Java and Moluccas, Batavia (to be capital of their eastern empire) in 1607, Malacca in 1641, Mauritius in 1644, Table Bay in 1652, and Ceylon (taken from the Portuguese) in 1658. By the end of the century their "factories" and forts were dotted all over the East – in the Persian Gulf, on the coast of India, and the Malayan archipelago. The EIC was largely confined to Surat (1612), Madras (1639), Calcutta (1650), and Bombay (1665). This inequality of settlement numbers is also indicative of the different approaches to overseas trade at this time by the English and Dutch. In contrast to the VOC the EIC remained independent of direct state ownership (being answerable instead to company shareholders) and promoted its activities upon the basis of free enterprise.

By 1784 there was sufficient support in the British parliament for Prime Minister Pitt to introduce the *India Act*. The intention of which was to "...take care to prevent the Government from being ambitious and bent of conquest. Propensities of that nature had already involved India in great expenses, and cost much bloodshed. These, therefore, ought most studiously to be avoided. Commerce was our object, and with a view to its extension, a pacific system should prevail, and a system of defence and conciliation" (Pitt's speech in the House of Commons 6 July 1784 in Aspinall & Smith 1969: 826). The bill effectively gave the control of Company occupied lands to the British government by subordinating the Directors to a new government department, the Board of Control:

> It shall not be lawful for the Governors or Presidents and Councillors of Fort Saint George and Bombay...to...issue any order for commencing hostilities or...to negotiate...any Treaty...with any Indian Prince or State (except in cases of sudden emergency or imminent danger, when it shall appear dangerous to postpone such hostilities or Treaty) unless in pursuance of express orders from...Governor-General and Council...or from the...Court of Directors.... (clause XXXV of the 1784 *India Act* in Aspinall & Smith 1969: 830).

Following the Bill, trade to the East Indies was controlled by the newly organized United Company of Merchants of England and the sovereignty of India became Britain's responsibility. Thus, it was to begin that under the newly organized United Company of Merchants of England trading to the East Indies, the sovereignty of India became Britain's responsibility. By concentrating their main center in Java the Dutch had seceded any Indian interest to the English, and the French (who had not entered the competition until 1700s) lacked the support they needed to compete with the already established English.

Prior to the nineteenth century, Germany's maritime activity had concentrated upon internal European trade under the Hanseatic League. Preoccupation with the politics of unification also separated it from the kind of long-distance overseas trade enjoyed by other European rivals. During the nineteenth century, Germany's foreign policy was controlled by Chancellor Otto von Bismarck. Like the involvement of the other principal players in what was to become the *Scramble*

for Africa, movement into the African continent was instigated in equal parts by the desire to increase the nation's economic production in light of burgeoning industry and, by association, the need to maintain economic growth. It was also an attempt to balance internal European political and economic stability. By this note, Africa was for both Great Britain and Germany a tool by which to maintain a European equilibrium. This equilibrium was such a consuming matter that Bismarck himself later told a German explorer, "Here is Russia and here is France. . .with Germany in the middle. That is my map of Africa" (translated in Packenham 1991: 203).

By 1888 the British government was under pressure from antislavery campaigners and a conference in Brussels was convened under the guise of establishing civilizing legislation designed to end the scourge of the slave trade, but in reality was an opportunistic gathering together of the various European powers with a stake in the control of Africa. For the British government it was also used to reestablish naval supremacy in the Indian Ocean where the rights to stop and search vessels had not previously been fully realized between all nations, thus allowing for greater control of the movement of trade commodities and domination of the regional capitalist system.

The results of the conference were highly influential. For the first time, humanitarian concerns were addressed within an international political arena, with the measures agreed upon by the signatories affectively legitimizing colonial conquest through the agreed strategy of combating slavery by the establishment of colonial administration in the interior of Africa and the restructuring of African society. At the conference it was suggested by the Belgian delegation that the most effective way to establish such an administration was through the development of colonial infrastructure. This was to include the establishment of fortified posts in the interior to act as centers of refuge for emancipated slaves, as well as garrisons for troops able to pursue slave caravans. Roads and railways were to be constructed from the coast into the interior and steamboats were to be placed on navigable rivers and lakes. Although neither Britain nor Germany fully committed to these proposals, their discussion at the Brussels Conference was nonetheless later useful. When either government wished to propose large-scale infrastructure development in Africa it could now legitimately invoke the Brussels Conference and antislavery civilizing rhetoric.

This European drive to control overseas land and populations did not rest solely with Britain and Germany (though it was the antagonism of these two nations which was to drive other nations to develop their overseas "dominions" up to the twentieth century). Britain eventually controlled most of the subcontinent of India, Australia, New Zealand, Canada, and large areas throughout Africa (e.g., Sudan, Botswana, Kenya, Egypt, Gambia, Ghana, Nigeria, Zambia, Malawi, Sierra Leone, Zimbabwe, Swaziland, Tanzania, and Uganda). In Africa, France also controlled large areas throughout the continent (most notably Ivory Coast, French Sudan (now Mali), Guinea, Mauritania, Niger, Senegal, northeast Nigeria, Gambia, Chad, Republic of Congo, Gabon, Cameroon, Eritrea, Madagascar, Djibouti, Comoros, and Reunion). Germany controlled (among others) Burundi, Rwanda, Tanzania, and Namibia. With Italy dominating; Eritrea, parts of Somaliland and Libya.

Economic justification for national policies of colonialism and expansionism led in turn to global sociohistorical change through the development of class formation, political struggle, and cultural perceptions. The ultimate outcome of the Brussels Conference was therefore the partitioning of Africa into colonial blocks controlled by Europe and the full realization of the Second Phase of European Colonialism.

Key Issues/Current Debates

Central to this strand of social theory and postcolonial studies is the question of subjectivity. Accordingly there is a long tradition of Latin American intellectuals addressing this question. Among them were Dussel, Rodolfo Kusch (whose philosophy of Indigenous thinking as equal to European thought was published in

1970 but not translated into English until 2010), earlier still the "cannibal" movement in early twentieth-century Brazil, and the "Forja" movement in Argentina in the 1930s. During the 1990s, subjectivity and the ways in which people describe themselves to others also became a significant area of interest within archaeology and cultural studies (see, e.g., Hall 1996; Gosden 1999). The primary questions being related to identity, i.e., the process and manner in which individuals, groups, communities, cultures, and institutions define themselves. However, the debate as to the nature of the establishment of identity can be approached in two ways. First, one can argue for fixed categories based upon definable "foundational" differences. Or secondly, one can view one's perception of identity as a more fluid phenomenon based upon reaction/reflexivity and dialogue (both inner and outer) (Meskell and Preucel 2004: 122). This first taxonomical approach can be useful when it becomes necessary to quantify groups of individuals, but can stray into dangerous labels/pigeonholes and meta-identities. The second, more poststructural view approaches the formation of identity as involving the negotiation of "race," class, religion, sexuality, ethnicity, and gender, as well as the environmental and cultural context in which individuals find themselves. Constructivists would even go so far as to argue that identities do not exist but are in reality discursive constructs which are formulated through one's personal dialogue with one's sociocultural, physical, and political environment.

It is the nature of this dialogue and one's autonomy within it that has developed into a philosophical debate as to the role of the self in the formation of identity. In the past the two main protagonists within this debate are Foucault (1972) and Giddens (1991). Both agree that:

> . . .self-identity is negotiated through linked processes of self-exploration and the development of intimacy with the other (Giddens 1991: 97).

However, the debate rests upon the level of autonomy available to the individual within the multiple and competing discourses within the postcolonial/colonialist world. Foucault (1972) argues that the individual is subservient to the dominant social discourse, which is based upon the power of shared knowledge. Alternatively, Giddens' (1991) views the individual within society as less the passive participant and more the creative transformer:

> The self is not a passive entity, determined by external influences; in forging their self-identities, no matter how local their specific contexts of action, individuals contribute to and directly promote social influences that are global in their consequences and implications (Giddens 1991: 2).

Giddens' *structuration theory* (1991) gives the individual an understanding of the social context in which they exist and allows for reaction against it. This not only allows for one to develop multiple situationist identities but also allows for the idea that individuals have an indelible political and social autonomy. This is a concept central to the postcolonial debate on the role of participants in colonial activity. Furthermore, the search for identity, be it individual or society, requires a meta-narrative in order to formulate a dialogue between life experience (meta-narrative) and perception (the self). This meta-narrative takes the form of *culture* while *cultural identity* is the extent to which one is representative of a given culture behaviorally, communicatively, psychologically, and sociologically.

All of these theoretical strands exist within the history of the development of postcolonial identities or, more specifically, the international politicization of identities in the twentieth century. As Hall (1990: 225-26) demonstrates in an essay addressing the African diaspora, wrestling control of contextualizing metanarratives is central to the struggle for equality:

> Not only, in Said's 'Orientalist' sense, were we constructed as different and other within the categories of knowledge of the West by those regimes. They had the power to make us see and experience *ourselves* as 'other'. Every regime of representation is a regime of power formed, as Foucault reminds us, by the fatal couplet, 'power/knowledge' (Hall 1990: 225–26).

International Perspectives

As can be seen from this short explanation of Second Modernity and the Second Phase of

European Colonialism, although the social theory and events described above were born within distinct geographical regions of the world (i.e., Africa and Latin America), they possess the common linkage of having been the result of European action based on a capitalist development and world view. The commonality of the two is in the need to recognize the role of the colonized and its impact on the perceptions of Europe and its activity and the manner in which we have subsequently addressed non-European cultures from a dominantly European foundation.

This is a phenomenon that is reflected in the development of archaeology as a practice and it is important to recognize the nature of the "constructedness" within archaeology. The practice and debate of archaeology worldwide has not taken place in a vacuum immune to the influences of those ideas outlined thus far. Likewise, these ideas have not developed without the influence of archaeological and historical knowledge. Archaeology began as a Western colonial science, with a role in the conquest of territories and peoples (represented by antiquarian styled exploration and collection). It has become, through the application of deconstructive philosophies, a potential tool for the study, definition, and voice of subaltern or less well-represented groups within Western-dominated historical narratives, with specific strands of "new" archaeologies (such as historical archaeology – see discussion below) specifically attempting to construct non-European cultural narratives developed outside the world of historical and cultural colonialism.

Future Directions

Our current understanding of colonial processes is largely based upon the development of Western anthropologists. More recent studies have begun to question traditional colonial ethnographies and their close link to colonial powers (e.g., Comaroff and Comaroff 1992; Barker et al. 1994; Mignolo 1995; Benjamin 2002; Gasco 2005). What these studies have in common is their rejection of binary oppositions in colonial discourse. By rejecting the traditional historical view of the "colonizer" and the "colonized," new ideas of sociocultural hybridity have developed in response to the recognition of new societies created through the colonial process. The problematization of these traditional discourses has developed into what we now term postcolonial theory:

> Colonialism broadly conceived, or 'coloniality', when seen as a process including territorial expansion and imperialism, labour regulation processes, and epistemological and discursive 'reorganization', is not therefore only current because of territories which are still formally colonial, but because the relations of difference that mark the 'colonial' period are still very much in operation throughout the world, particularly in the West and wherever 'the West' and its epistemology asserts itself, i.e.: globally (Benjamin 2002: 15).

The second definition of postcolonial theory as an ideological application has been separated by Goldberg and Quayson (2002: xii-xvi) into three interrelated sets of ideas of particular relevance to the question of Second Modernity and the spread of Western capitalism via colonial activities.

Postcolonial study possesses a "theoretical expansiveness" by the way in which it aims to adopt the voice of "otherness" included within all experiences. With this approach the author would promote the role of archaeology and specifically historical archaeology as a means of addressing and examining accepted definitions of social and cultural activity within the colonial context (see Rhodes 2010). It may therefore be that archaeology of the traditionally historic period is able to attempt to strip our understanding of the past of its historical prescription through analyses of subaltern material evidence. Or at least offer new ways of viewing the historic colonial past as long as the unavoidable embedded bias of cultural perspective is recognized and deconstructed along with received historic narratives.

So what of the application of these definitions to the development of non-Western archaeologies? First is the rejection of meta-narratives. Although archaeology is well suited to address the actual material processes of European colonial activity over a large geographical scale, the aim should not be to lay claim to a totalizing knowledge of this process. The author would echo the

so-called *Frankfurt School* and the development of *critical theory* (see, e.g., Hodder 1986, 1992 and Shanks and Tilley 1987), with its recognition of the historically conditioned nature of studies of the past, and accept that all archaeological research stands within a specific context and is generated form a specific world view but, nonetheless, aims to highlight shared characteristics within (perceived) events and activities in the past. As Foucault argues, the aim is to demonstrate the nature of discourse within a given context:

> Instead of following the thread of an original calendar, in relation to which one would establish the chronology of successive or simultaneous events, that of short or lasting processes, that of momentary or permanent phenomena, one tries to show how it is possible for there to be succession, and at what different levels distinct successions are to be found (Foucault 1972: 169).

Furthermore, archaeology exists within the postcolonial paradox, by openly beginning from the ideological position of defining one people at the rejection of others. It is hoped that active investigation of the remains of the past in a more ethically transparent way than has been previously attempted can offer a newer and broader insight into the past. The intention is that by applying archaeological techniques to an area that has previously seen little investigation outside traditionally historical interpretation newer perspectives can be created.

Can this be achieved? What is required is the application of a unifying approach which allows for the development or sharing of postcolonial strands of archaeological study over more globally inclusive geographies. This is to say that the issues raised by the experience/history/activity/narrative of colonialism exist in many places and over a wide temporal sphere (the examples above being Latin America and Africa). Dialogue between historically peripheral groups (that is to say groups not focused upon by European-led investigations) would seem the next step in developing truly non-capitalist global heritages. But this is not to say that all "new" or "subaltern" heritages should be essentially reactionary or counter colonial. Rather, scope should be given to define the internally heterogeneous character of cultures based on the ever re-negotiated identities.

Second Temple Judaism Archaeology

Mark A. Chancey
Department of Religious Studies, Southern Methodist University, Dallas, TX, USA

Introduction

The term "Second Temple Judaism" refers quite literally to the period of Jewish history when the second Jewish temple stood in Jerusalem, c. 515 BCE to 70 CE. The first temple, traditionally attributed to the Israelite King Solomon in the tenth century BCE, had been destroyed by the Neo-Babylonian Empire during its conquest of the region, c. 586 BCE. When the Achaemenid Persian Empire defeated the Babylonians, it acquired the southern part of the Levant associated with modern Israel, Palestine, and adjacent areas. The Persians allowed Jews to rebuild their temple, c. 515 BCE, and it stood until c. 70 CE, when the Romans destroyed it while suppressing a Jewish uprising, the First Revolt. Jews in the Second Temple period experienced rule by the Persians, Alexander the Great, the Ptolemies, the Seleucids, an independent Jewish dynasty known as the Hasmoneans, and the Romans, who administered Palestine through both appointed Roman officials as well as the Herodian dynasty of client kings. The era was formative for the development of Judaism, as various biblical works were composed and revised, a scriptural canon was nearly finalized, diverse Jewish sects flourished, Jewish territory expanded, and Jewish society was thoroughly integrated into the larger cultural matrix of the Mediterranean world. Although this period also saw the increasing dispersal of Jews beyond their traditional homeland to areas ranging from the Italian peninsula to North Africa to Asia Minor to Mesopotamia, this entry will focus primarily on the area known variously as Israel or Palestine, where evidence is more abundant. In general, more archaeological data is available for the later centuries of this period than for the earlier ones, particularly in regard to religious practices. Historians are fortunate to have not only the archaeological record but also numerous literary sources written from various perspectives.

Historical Background

Biblical sources credit the Persian King Cyrus II for allowing Jews exiled to Mesopotamia by the Babylonians to return to Jerusalem and the surrounding area of Judah beginning c. 538 BCE. Scholars have often cited the famous cuneiform inscription on the Cyrus Cylinder, found in

Babylon in the nineteenth century, as supporting evidence for a Persian policy of returning subject peoples to their native lands. The deportees returning from Babylonia, which were likely a small group, joined with Jews who had remained behind in rebuilding Jewish society and its primary city, Jerusalem. Yehud was the Aramaic name of the Persian province in which they lived, which was a subunit of a much larger Persian satrapy. The exact boundaries of Yehud are disputed, but it is obvious that it was fairly small and limited to the areas surrounding Jerusalem. Its initial population was correspondingly small. Although scholars once proposed that in the late sixth and early fifth centuries, Jerusalem, the major population center, had as many as 5,000–7,000 inhabitants, more recent estimates have been as low as 1,250 or even 400 (Meyers and Chancey 2012). What is clear from both surveys and excavations is that the Persian era inaugurated a period of population growth that would continue for centuries. Biblical sources suggest that construction of the Second Temple began c. 515 BCE, although virtually no archaeological evidence of the structure from this period survived due to the extensive renovations carried out later by the Hasmonean and Herodian kings.

Persian-period finds of various categories (architecture, local pottery, imported pottery import from Greece and the Eastern Mediterranean, inscriptions) from the southern Levant are abundant and have been the subject of considerable scholarly interest since the 1980s, largely due to the publication of an impressive archaeological synthesis by Ephraim Stern. Coins had already entered the region in the early sixth century but became more common under Persian rule. The province minted its own coins, marked by the Aramaic inscription YHD ("Yehud") and decorated with various images including the Athenian owl, the Greek deity Arethusa, griffins, and the Persian kings. Jars and jar handles from multiple sites bearing stamps reading "Yehud" in Aramaic and Paleo-Hebrew scripts were probably components of a tax-in-kind system. Many "Yehud" seals and seal impressions have also been discovered, sometimes accompanied by personal names and administrative titles. Efforts have been made to associate some of the names on the Yehud seals and coins with Jewish figures; it is possible, for example, that the figure "Yehohanan the priest" mentioned in inscriptions was a Jewish priest. The use of Aramaic characters on coins and seals reflects the importance of the language as the Persian lingua franca. Aramaic grew in importance as a written and spoken language throughout the Second Temple period, eventually displacing Hebrew as the primary Jewish language, and the Aramaic script became standard even for most Hebrew texts. That the inhabitants of Yehud held distinctive religious views is demonstrated by the general lack of figurines and cultic objects, which are common finds in surrounding areas (Stern 1982; Betlyon 2005).

The most important evidence from the Jewish Diaspora in this time period comes from the Egyptian island of Elephantine, located in the Nile River near Aswan. Papyri associated with the site preserve letters and legal documents from a garrison of Jewish and Aramean mercenaries stationed there. The military colony had a temple devoted to the Jewish deity YHWH, demonstrating that the later Jewish belief that animal sacrifices could only be carried out in Jerusalem had not yet fully developed. One papyrus preserves instruction regarding unleavened bread that is generally interpreted as a reference to the Jewish Passover festival (Porton 1996; Betlyon 2005).

Alexander the Great famously conquered the eastern Mediterranean coast in 332 BCE. The years between his conquest and that of the Romans in 63 BCE are known as the Hellenistic Period. After Alexander's death (323 BCE), Palestine lay at the meeting point of two of his successor kingdoms, the Ptolemies, based in Egypt, and the Seleucids, situated in Syria and parts of Asia Minor. The Ptolemies initially possessed Palestine until the Seleucids gained possession c. 200 BCE. Jews threw off Seleucid rule in the Maccabean Revolt, which began in 168 BCE, and from the leadership of that rebellion emerged a Jewish royal dynasty, the Hasmoneans.

Under the Ptolemies and the Seleucids, Hellenistic (Greek) influence in Palestine increased steadily, becoming a dominant component of Jewish and other local cultures in the region for the

next thousand years. The minting of coins with Semitic inscriptions in Jerusalem initially continued in the Ptolemaic period but then ceased. Aramaic inscriptions YHD and YRSLM ("Jerusalem") appeared on jar handles, but such pottery was soon be joined by amphora handles with Greek stamps imported from the eastern Mediterranean (Arav 1989; Berlin 1997; Tal 2005). Papyrological records associated with Zenon, a third-century BCE agent of the Ptolemaic finance minister, shed light on government holdings and agricultural practices in Palestine, and numerous other papyri attest to the varying fates of Jews in Egypt, some possessing land and wealth, others working as artisans, peasants, and land tenants. Greek inscriptions in Ptolemaic Egypt attest to the existence of buildings there known as *proseuchai*, Jewish prayerhouses (Tcherikover et al. 1957–1964).

Under the Hasmonean dynasty, Jewish territory expanded considerably. With their Seleucid foes weakened, the Hasmoneans pushed in all directions, stretching Jewish territory far beyond the environs of Jerusalem to include Samaria (roughly equivalent to the modern West Bank), Galilee, portions of the Negev, and parts of modern Jordan. Archaeological findings sometimes corroborate literary reports of Hasmonean conquests. Evidence of destruction probably associated with Hasmonean campaigns has been found at sites including Gezer, Tel Istabah near Beth-Shean, Ashdod, Shikmona, and Maresha. In Samaria, a Persian-period temple on Mount Gerizim overlooking Shechem was completely destroyed. By the early first century BCE, Hasmonean forces had taken Galilee, which subsequently became a predominantly Jewish region. Surveys and excavations there have revealed the abandonment of older sites, the establishment of new ones, and dramatic changes in the ceramic repertoire that are best explained by population shifts (Berlin 1997; Tal 2005; Meyers and Chancey 2012).

The general parameters of Hasmonean territory can be traced by finds of their coinage. They minted numerous bronze issues of varying weights and sizes, typically employing Attic denominations, as had the Seleucids, rather than using Phoenician standards. Hasmonean coins differed from most other regional coinage in their less prominent use of Greek. Many coins had Hebrew inscriptions written in Paleo-Hebrew script, symbolically connecting the dynasty with earlier Jewish history, though some had Aramaic legends and those of later kings also used Greek. The symbols on Hasmonean coins also differed from those of surrounding minting authorities in their avoidance of anthropomorphic and zoomorphic imagery. They instead displayed symbols often drawn from the standard Mediterranean repertoire, such as cornucopiae, a lily, and an anchor. Only coins from the last Hasmonean ruler, Mattathias Antigonus, had what might be described as uniquely Jewish symbols: some depicted a menorah, while others portrayed an image often interpreted as cultic furniture from the temple, the Showbread Table. The names and titles on Hasmonean coins also show how Jewish and broader Hellenistic culture interplayed. Early coins bore rulers' Semitic names; only later issues were inscribed with their Greek names. The title of "king" did not appear until the first century BCE, but the title of "high priest" appeared throughout the Hasmonean era, and claims to be the "head of the council of the Jews" marked the currency of some rulers (Meshorer 2001).

Jerusalem grew considerably in the Hasmonean era, stretching beyond the area adjacent to the temple westward onto modern Mount Zion. The Hasmoneans enclosed the city's new territory with a major defensive wall equipped with additional towers. They also undertook occasional renovation of the temple complex, and some attribute particular ashlars in its eastern retaining wall to them because their crude bosses are similar to other Hasmonean masonry. Elites in the city constructed lavish tombs that closely resembled monumental tombs elsewhere in the Hellenistic world, advertising their political stature and wealth. Two of the better-known examples include the tomb of Benei Hezir, which stood just outside the eastern walls of Jerusalem, and the tomb of Jason, located west of the walls. The first is known for its red-painted Hebrew inscription associating it with "priests of the sons of Hezir," a family mentioned in the biblical books

1 Chronicles 24:15 and Nehemiah 10:21. Its interior chambers had the types of burial slots that would be typical of Jewish tombs for centuries, loculi (niches cut perpendicular into the wall) and arcosolia (shelves cut parallel to the wall). Doric motifs and a pyramid decorated its exterior. A pyramid and Doric motifs also marked Jason's Tomb, located west of the city. The walls of its porch bore an Aramaic and a Greek inscription as well as charcoal drawings of a ship, a palm branch (an early example of a symbol that comes to typify Jewish art), and five menorahs that are among the earliest images of the temple candelabrum. In addition, a drawing of a stage shows that not all Jews avoided figural representations of living things, suggesting that modern notions of strict ancient Jewish aniconism are an oversimplification (Berlin 1997; Levine 2002; Fine 2005; Hachlili 2005).

The Roman general Pompey's expeditions into the region started the Roman period, which lasted from 63 BCE until the mid-fourth century CE. The Romans quickly grew tired of infighting between the last members of the Hasmonean dynasty and appointed a new ruler from an entirely different family, Herod (variously called the Great or the First). Herod was a descendent of Idumeans who had converted to Judaism after the Hasmonean conquest.

Herod was deeply influenced by the massive construction he witnessed on his visits to Rome and became one of the most influential sponsors of Roman-style architecture in the Levant. In his own kingdom, he built a variety of monumental buildings, sports facilities, fortresses, and palaces that blended Roman, Hellenistic, and local styles. Roman construction and decorative techniques in his construction projects included *opus reticulatum*, the facing of walls with diamond-shaped blocks; *opus sectile*, the inlaying of multi-shaped and multicolored stone tiles on floors; mosaics with Roman-style floral and geometric designs; and frescoes with colored panels, stripes, dots, and patterns that resembled those in Pompeii (albeit without the images of humans, animals, or mythological characters found there). Limited Greek-style bathing facilities had entered Palestine in the Hellenistic era, but Herod's palaces had Roman baths with multiple chambers devoted to different temperatures and the use of hypocaust technology for warming (Netzer 2008).

Herod's embrace of Roman culture is visible in the layout of the new city he built on the Mediterranean coast outside of Jewish territory. Named Caesarea Maritima after the emperor, the city's streets were organized on a grid, like other typical Roman cities. Its buildings included a long oval-shaped structure that was either a stadium for foot races or a hippodrome for horse and chariot competitions and a 3,500–5,000 seat theater, built in a half-circle shape with a back wall behind the stage, as per Roman conventions. The new harbor reflected the most advanced technology of his day, with long breakwaters consisting of concrete blocks made of hydraulic cement. The centerpiece of the city was a temple dedicated to the emperor standing on a massive platform that made it easily visible from sea; it was one of the earliest temples of the imperial cult anywhere in the Roman Empire. It was one of three such temples Herod built; the others were at Banias, known in antiquity as Paneas and briefly in the first century CE as Caesarea Philippi, and at Sebaste, a new Roman-style city built at the site of the ancient city Samaria (Netzer 2008).

Herod also strengthened the fortifications of Jerusalem. The lower courses of the so-called Citadel of David now visible at Jerusalem's Jaffa Gate are remnants of a Herodian tower, as are walls visible in the adjoining courtyard. By far, the best known of Herod's projects in Jerusalem, however, is his extensive renovation of the temple and the platform on which it stood, known in Jewish tradition as the Temple Mount and in the Islamic world as the Haram al-Sharif. Herod's engineers expanded the platform northward, westward, and southward; eastern expansion was impossible because of the steep Kidron Valley. Clear evidence of the southern extension can be seen in the eastern retaining wall, where a vertical "seam" separates Herodian ashlars from earlier ones. The size of the modern Temple Mount is largely due to Herod's construction; it measures roughly 315 m on the north, 280 m on the south, 485 m on the west, and 470 m on the east. The retaining walls, of which the most famous is the

Western Wall, were themselves massive. Built from local limestone, most of their blocks weighed at least several tons, and some, such as the 14-m long and 4-m high example in a tunnel running along the Western Wall, weighed much more. A special station stood up top of the wall at the southwestern corner for the blowing of the traditional Jewish shofar, as indicated from the discovery of a corner block with the Hebrew inscription "the place of trumpeting. . .." Huge staircases led up to two gates (their outlines still visible) on the southern side of the temple complex, and evidence of four gates has been found on the western side. Porticoes lined the four sides of the courtyard atop the Temple Mount, their existence reflected in the many column fragments found in modern excavations; this extensive use of columns reflected both Hellenistic and Roman influence. Two copies of a Greek inscription have been found that marked the limits on the Mount beyond which non-Jews could not go upon punishment of death. As for the temple building itself, the presence of Islamic shrines (the Dome of the Rock and the Al-Aqsa Mosque) makes archaeological effort to recover it impossible. If, as is typically thought, silver coins from the Second Revolt against Rome (132–135 CE) with stylized representations of a temple preserve memories of its appearance, its facade had four columns and a cornice. Taken as a whole, the temple complex was the largest in the Roman Empire and one of the largest anywhere in the ancient Mediterranean and Near Eastern worlds (Bahat 1999; Levine 2002; Netzer 2008).

After Herod's death in 4 BCE, his territory was parceled out to his sons. Members of the Herodian dynasty would alternate with Roman prefects and procurators in governing his former territory, the complex administrative arrangements not stabilizing until after the First Revolt against Rome (66–73 CE). Herod's successors lacked his resources, though they still attempted their own building projects. His son Antipas, for example, who governed Galilee and Perea (east of the Jordan River) from 4 BCE to 39 CE, rebuilt the older city of Sepphoris (in Hebrew, *Zippori*) and established the new city of Tiberias (named after the emperor), both in Galilee. Modern habitation has limited the archaeological exploration of Tiberias, but excavations have recovered ample evidence of Jewish habitation at Sepphoris in the form of stone vessels and ritual baths (see discussion below). In the second century CE, Sepphoris would become a major center of Jewish thought as teachers known as rabbis settled there and began to compile traditions that ultimately were included in the rabbinic literature that became authoritative for Judaism. The site is noteworthy for the presence of Roman-style architecture (especially a theater) and art (most notably mosaics, including some with mythological imagery), although these appear to postdate the First Revolt, often by considerable margins (Meyers and Chancey 2012).

Like the Hasmoneans, the Herodian client kings minted bronze coins. Those of some, like Antipas and Archelaus, refrained from depicting living things, but those of others bore busts and images of either themselves, the Roman emperor, or members of the royal or imperial family. Coins of Philip had images of a temple usually interpreted as that dedicated to Caesar at Banias, while those of Agrippa II went so far as to depict classical deities; both rulers oversaw the northernmost parts of Herod's territory, where Jews were a minority. Most Herodian coinage had Greek inscriptions, although a few issues of Agrippa II had Latin (Meshorer 2001).

Jewish tensions with Rome ultimately led to the First Revolt (66–73 CE). The writings of the Jewish historian Josephus, who served first as a field commander of Jewish forces in Galilee and then as a translator for the Romans, are our primary literary source for understanding events (especially *Bellum Judaicum*; Williamson 1970). After initial successes, Jewish forces suffered a series of devastating defeats. In the north, the aftermath of siege warfare in 67 CE is clearly visible at the Galilean site of Yodfat (in Greek, Jotapata) and at Gamla, in the southwestern Golan Heights. Archaeological finds at the hilltop village of Yodfat include fortification walls, arrowheads, ballista stones, a rolling stone, other pieces of weaponry, portions of a siege ramp, and skeletal remains. Finds at Gamla are similar: some 2,000 ballista stones, 1,600 arrowheads, and 100 catapult bolts, as well as large stones dropped and

rolled by the defenders down the steep ravines surrounding the site. Fortification walls are still clearly visible, including a major breach near the village synagogue. The town struck its own bronze coins during the revolt, each bearing the defiant Hebrew inscription "For the redemption of H[oly] Jerusalem" (Meshorer 2001; Berlin and Overman 2002).

Jerusalem was the site of the fiercest combat. Jewish forces there issued both silver and bronze coins with the Paleo-Hebrew inscription "Jerusalem the Holy," but they were not be able to defend the city against the Romans' overwhelming strength. Roman forces succeeded in entering the city and destroying the Second Temple in 70 CE. Excavations carried out since the Israelis gained possession of the Old City in 1967 have found ample evidence of widespread destruction in the elite residences of the Herodian Quarter west of the Temple Mount. In the so-called Burnt House, everyday domestic items lay scattered on the floor, a spear leaned against a wall, and the bones of a woman's forearm and hand remained stuck in the debris. South and west of the Temple Mount, extensive rubble lay on Roman-period streets, consisting of ashlars, pieces of columns, and other architectural fragments thrown down by the Romans as they dismantled the buildings of the sacred precinct above (Berlin and Overman 2002; Levine 2002).

In 73 or 74 CE, Roman units moved east into the Judean wilderness near the Dead Sea to complete their victory by mopping up the last of the Jewish resistance. The chief battle there occurred at the old Herodian fortress of Masada, built atop a massif. Josephus famously records that after a lengthy siege, Masada's Jewish defenders committed suicide rather than allow the Romans to claim a victory, though some modern scholars question the veracity of this account. The outlines of the Romans' siege wall surrounding the site can still be seen today, along with a 4,500-m long siege ramp and the rectangular boundaries of their military camps. A remarkable amount of military equipment has been found, including pieces of scale armor, helmets, spearheads, arrowheads, fragments of swords, and ballista balls (Berlin and Overman 2002).

The Romans advertised their victory over the Jewish rebels by striking coins proclaiming "Iudaea Capta." The Arch of Titus in Rome portrays legionnaires triumphantly carrying plunder from Jerusalem, including the menorah from the temple (Berlin and Overman 2002). The Second Revolt against the Romans under the leadership of Bar Kokhba in 132–135 CE would also prove unsuccessful and end Jewish attempts to reclaim Jerusalem and rebuild the temple.

Key Issues and Current Debates

Among the chief discoveries in recent decades is the ample evidence of ancient Jewish interest in ritual purity. One reflection of this interest was the construction of small pools generally interpreted as ritual baths (in Hebrew, *miqva'ot*) because of their general similarity to the descriptions of such baths in rabbinic sources. Ritual baths were stepped, plastered pools cut into bedrock. Their sizes varied, but they were generally deep enough to allow full immersion of the body and were sometimes accompanied by a small storage pool to the side. Although the practice of ritually cleansing oneself through immersion is attested in the Hebrew Bible, the appearance of pools built specifically for this purpose was a new phenomenon of the Hasmonean period. By the first century CE, *miqva'ot* were numerous throughout Judea, and examples have also been unearthed in Galilee and in the Golan at Gamla. Ritual baths are found in Herodian palaces, where they served as the cold pool (in Latin, *frigidarium*) of Roman-style bathing facilities; on major roadways near Jerusalem, perhaps for the use of pilgrims; at various points in the vicinity of the temple; near synagogues (such as that at Gamla); near cemeteries (possibly to help remove impurity contracted by contact with or proximity to corpses); in association with wine and oil presses to facilitate production of pure juice and oil; and in both rural and urban domestic contexts (Berlin 2005; McCane 2010).

A related phenomenon was the use of limestone vessels, which rabbinic texts describe as impermeable to ritual impurity. These vessels were found in a variety of forms, including jar

stoppers, mugs, kraters, bowls, and large storage jars. Most were clearly intended to hold and thus keep pure liquids. Their manufacture and use quickly extended beyond Jerusalem to other parts of Palestine, and whole vessels or fragments have been found at dozens of sites in Judea and Galilee, in both cities and villages and in the residences of both elites and commoners. Stone vessels are generally absent from sites in Samaria or in surrounding areas that were primarily inhabited by non-Jews (Berlin 2005). Yet to be answered in regard to both limestone vessels and miqva'ot is whether differences in practices between Jews associated with various sects (Pharisees, Sadducees, Essenes) or no sect can be identified archaeologically.

Another new phenomenon of the late Second Temple period was the use of small sarcophagi known as ossuaries for secondary burial. For reasons not yet clear (typical explanations appeal to views of the afterlife, hopes for the expiation of sins, or increasing emphasis on individual identity), some Jews began gathering up the bones of the deceased after the flesh had decayed (roughly a year's time) and placing them in ossuaries. Although the practice of secondary burial within Judaism is attested earlier, the creation of special receptacles for the purpose is apparently unprecedented. Most ossuaries were made of limestone, but ceramic examples are also known. Ossuaries have been discovered at sites in Judea, Samaria, and Galilee. The rate of their geographical diffusion is unclear, as is the date for the end of the practice; once thought to be the end of first century, it now clearly extends into second. Aside from coins, ossuaries are the single most common source of Jewish inscriptions from this time period. Typical content of these inscriptions includes the name, place of residence or origin, and names of family members of the interred. Most are in Aramaic or Hebrew, though roughly a third are in Greek and a few in Latin (Hachlili 2005).

Scholarly understanding of the early history of the synagogue has also made significant advances. Synagogues were categorically different from the Jerusalem temple. For most Jews, the temple was the only place where animals could be sacrificed. In contrast, many towns and villages had synagogues, in which where the local Jewish community gathered for worship, study, and public meetings. The earliest evidence of synagogues comes from Ptolemaic-period Greek inscriptions from Egypt referring to *proseuchai* (houses of prayer) and from a first-century BCE structure often interpreted as a synagogue on the Greek island of Delos. Several likely examples from the late Second Temple period have been found at sites in Israel, including Gamla, Masada, Herodium, Kiryat Sefer, Modi'in, and most recently, Magdala. In addition, the first-century CE Greek inscription from Jerusalem known as the Theodotus Inscription provides important information about a synagogue there. It identified the primary activities associated with the synagogue as teaching about the Law (the Jewish Torah) and the commandments and providing hospitality to strangers, and it mentions three generations of *archisynagogoi* (rulers of the synagogue) (Cotton et al. 2010: 53–6). Jewish and Christian texts make clear that numerous other synagogues existed by the first century CE, but at present, they are difficult to identify in the archaeological record. A wave of construction beginning in the late third century CE resulted in the creation of over a hundred synagogues in Israel (Levine 2000; Meyers and Chancey 2012).

Like later synagogues, those from the pre-70 CE period are square or rectangular, with benches around their interior walls and columns that sometimes made aisles. Unlike later synagogues, they generally lack inscriptions, extensive decorations such as mosaic floors or external friezes, special shrines to hold the Torah scroll, or the raised platform known as a bema. An excellent example is the Gamla synagogue, which was destroyed in the First Revolt. Built of local basalt, it measured 13.4 by 9.3 m. Columns lined all four interior walls, their capitals in the Doric style, and those in the corner cut in the shape of hearts. Benches provided seating for perhaps 150 people (Levine 2000; Meyers and Chancey 2012).

Aside from Jerusalem, no single site has proven as important for understanding Second Temple Judaism as Qumran, a set of ruins found

in the desert less than a mile west of the Dead Sea. The complex there included a tower, a pottery workshop, common dining area, cisterns, and large pools that are usually interpreted as communal ritual baths. A cemetery with roughly 1,200 graves lay nearby. The community was destroyed in the First Revolt, probably in 68 CE. Hidden in caves adjacent to the site were the over 900 manuscripts now known as the Dead Sea Scrolls, which were discovered in the late 1940s and the 1950s. The scrolls were mostly of parchment, though some were made of papyrus. They included a remarkable range of Hebrew, Aramaic, and Greek texts, with fragments of every book of the Hebrew Bible except Esther, apocryphal and pseudepigraphical books, rewritten scripture, commentaries on biblical books, apocalyptic works, astrological texts, legal texts, and liturgical texts. Some scrolls contained sectarian writings describing beliefs and practices similar to those of the Essenes, a group known from other literary sources. On the basis of the proximity of the caves to Qumran and the presence at both sites of an unusual ceramic form, a large lidded storage jar, most scholars have concluded that the group living at Qumran in antiquity was an Essene community. Other scholars, however, dispute the identification of the sectarian writings as Essene and question the wisdom of interpreting the settlement site primarily through the lens of the scrolls. Alternative theories regard the ruins as originally an agricultural villa, a fortress, a center for pottery production, or a trade station (Schiffman and Vanderkam 2000; Meyers and Chancey 2012).

The end of the Second Temple period marked a major transition in the historical development of Judaism. The religion continued its transformation from a tradition centered on a sacrificial cult to one focused on the teachings and practices prescribed in sacred texts such as the Hebrew Bible and rabbinic writings, which were composed in the centuries following the temple's destruction. Although memories of the temple and hopes for its restoration have played key roles in subsequent Jewish theology and liturgy, by the end of the Roman era the synagogue had emerged as the religion's dominant communal institution.

Secondary Products and the "Secondary Products Revolution"

David C. Orton
Institute of Archaeology, University College London, London, UK

Introduction

The term "secondary products" was coined by Andrew Sherratt in 1981 to refer to three resources that can be provided by livestock prior to slaughter: milk, wool, and labor. He saw these as components in a post-Neolithic "Secondary Products Revolution" (SPR) that fundamentally changed the economic bases of pre- and protohistoric societies in the Near East during the fourth millennium BCE, before spreading to Europe by diffusion: systematic production of milk and wool rendered specialized large-scale pastoralism (geared toward exchange) feasible; cattle-drawn plows permitted both intensification of agriculture and expansion of cultivation to previously marginal soils; and wheeled vehicles pulled by livestock allowed transportation of both arable and pastoral products in bulk.

Sherratt was in fact building on arguments by previous researchers that milking and wool use were not part of the original "Neolithic package," but rather later developments (e.g., Bökönyi 1974). However, by bringing these two strands together with animal traction; by setting out a detailed model of their economic implications; and by providing testable hypotheses regarding the timing and geography of this putative revolution, Sherratt set an agenda within economic prehistory that remains relevant more than 30 years on. There is some dispute as to whether this model requires the use of secondary products to be a unified post-Neolithic complex of *innovations*, or whether the SPR should rather be seen in looser terms as a revolution in the *scale* of their exploitation (see, e.g., Greenfield 2010). While research over the last three decades has steadily undermined the former, stricter view, there remains considerable empirical support for the broad thrust of Sherratt's argument.

In the decades since the phrase was first coined, the concept of secondary products has caught on more widely and has been expanded to include other preslaughter resources such as blood, hair, and dung. Beyond the geographic and temporal limits of the SPR model itself, Sherratt's ideas have focused the attention of zooarchaeologists and other researchers on the refinement of techniques for characterizing the nature of animal husbandry. The terminology inherited from Sherratt is perhaps unfortunate here: the "secondary" in his SPR referred to the hypothesized *chronological* precedence of exploitation for "primary products" (i.e., meat, fat, hide, and bone) over that for milk, wool, and traction, rather than to the

relative importance of pre-slaughter and post-slaughter products. Taken out of this context, however, one must be careful to avoid the erroneous implication that pre-slaughter products are necessarily secondary to meat as a motivation for raising livestock.

Definition

"Secondary products" refers to all resources that can be extracted from domestic animals during their life as opposed to after death, including milk, blood, dung, fiber, and labor/traction. The term has sometimes been extended to certain processed plant products such as olive oil and wine, but is used here only for resources derived from animals.

The "Secondary Products Revolution" is a specific model of economic change set out by Andrew Sherratt with regard to European and Near Eastern pre/protohistory. It holds that a complex of exploitation of several secondary animal products (namely, milk, wool, and traction) spread across the region in the Chalcolithic and Bronze Age, allowing both intensification and extensification of agriculture, promoting development of specialized pastoralism, and ultimately playing an important role in the development of complex societies.

Key Issues/Current Debates/Future Directions/Examples

Milk and Dairying

Of the three secondary products that were central to Sherratt's original argument, milk (and by extension the wide range of foodstuffs derived from it) has probably received the most attention in the literature. Of the four main Eurasian Neolithic domesticates, three – cattle, sheep, and goats – can practicably be milked, with horses later added to this number.

Far from being a purely post-Neolithic development, lipid residue analysis (see below) has now provided fairly conclusive evidence that milking was practiced to some extent from the beginning of the Neolithic in the Near East and southeast Europe (Evershed et al. 2008). It should be stressed, however, that more than a single innovation was required for it to become a major component of husbandry strategies. For one thing, full adult lactose tolerance remains the exception rather than the rule for human populations globally, and its contemporary prevalence in – for example – northwest Europe is believed to have been driven by selection pressure resulting *from* the availability of ruminant milk. In most Neolithic contexts, the contribution of milk to adult diet would thus have been dependent on the development of fermented milk products – cheese, yoghurt, etc. – in which the lactose is broken down.

Meanwhile, Neolithic livestock would not have produced much more milk than was required by their infants, leaving little for human consumption. In recent dairy herds, most young are slaughtered very early to avoid competition, and this pattern is sometimes sought as a signature of dairying in zooarchaeological mortality profiles (see below). The ability of cows to let down milk without the presence of their own offspring appears to have been a recent development, however (McCormick 1992), and in prehistoric herds, milking probably required calves to be kept alive (the situation for sheep and goats is less clear). Calves might nonetheless have been weaned early to increase the milk available for humans: isotopic evidence from French Neolithic cattle indicates fairly early weaning, at around 6–9 months (Balasse and Tresset 2002).

Fiber

While the milk production potential of early domesticates is debatable, the situation for wool is starker: wild sheep simply do not have woolly fleeces, and it must have taken many generations for domestic populations to develop them. The fine fibers that form the undercoat of wild sheep eventually came to make up the bulk of the fleece, replacing the much coarser outer hair, but despite being the subject of considerable research, the timing of this process remains poorly understood. Although surely a gradual development, the key point from a technological point of view was

probably the emergence of wool that could be spun in the same way as flax. The present data seem to uphold Sherratt's view that this was a fourth millennium phenomenon in the Near East (see review in Greenfield 2010), although an earlier date cannot be ruled out. The subsequent spread of woolly sheep across Europe and Asia remains poorly resolved, but appears to have been fairly rapid.

As with milking, specialized production of wool has certain implications for herd structures. Both male and female individuals are likely to be kept alive into adulthood, and the former may also be castrated to improve the quality of their fleeces while facilitating management.

Of course, wool is not the only animal fiber: sheep hair may have been employed for various purposes before it became fine enough to spin, while the use of goat and horse hair in more recent periods is well attested. Nor are sheep the only woolly domesticate: llama wool has a long history of use in the Andean region, as does alpaca fiber (Mengoni Goñalons and Yacobaccio 2006).

Labor

In the present context, labor refers to the use of domesticates as draught- or pack-animals and for riding. Within the geotemporal range of the SPR model, the implicated species are cattle, horse, donkey, and camels (both Bactrian camel and dromedary); elsewhere, other bovines, South American camelids, reindeer, and the Indian elephant can be added to the list.

The development of the cattle-drawn plow is at the heart of the original SPR model, in which it is held to represent a fundamental shift in the relationship between plant and animal husbandry (Sherratt 1981, 1983). Yoking cattle to ards (and later to moldboard plows) allowed for effective cultivation of heavier soils, greatly increasing both the fertile land available for arable crops and the productivity of land already under cultivation.

As with exploitation of caprine fibers, the use of cattle for traction might be expected to increase the value of adult animals – particularly castrated males (oxen) – and hence to promote delayed slaughter. This depends on the scale of stockkeeping and its relationship with arable farming, however, and in many circumstances, it may be more economic to use cows for traction than to support dedicated plow oxen that neither breed nor provide milk (see Isaakidou 2006: 108). A recent survey of draught cattle use through time noted substantial global variation both in the age/sex of animals used and in the degree of training involved (Johannsen 2011).

If cattle can pull plows then they can also pull carts, and figurine evidence suggests that the first wheeled vehicles were cattle-drawn. Within the SPR model, the development of carts allowed for bulk transport of agricultural and pastoral products and was thus important to the development of extensive production and provisioning systems (Sherratt 1981). The domestication of equids and camelids and their use as pack-animals is seen in the same light, although it seems likely that cattle had been used as *ad hoc* beasts of burden during the Neolithic (Greenfield 2010: 39).

Other Secondary Products

The use of blood from living animals is well-attested in the ethnographic record, particularly among cattle pastoralists. As with milk, blood represents one way of extracting sustenance from herds without reducing their numbers, although it requires considerable skill to carry out without endangering the animal. Unlike systematic milking, however, blood use need not have any impact on herd management.

Perhaps the most overlooked secondary product is dung, despite its often substantial role in agriculture. This may be because its use as fertilizer does not require any real technological innovations or specialized husbandry practices and is thus likely to have begun with the first animal husbandry. Manuring may have played an important role in the Early Neolithic of central and southeast Europe, for example, where intensive garden agriculture was probably integrated closely with small-scale herding (Bogaard 2005). Insofar as the shift toward extensive pastoralism implied by the SPR represented a spatial separation of caprine herding from agriculture, it may in fact have reduced the role of manure. That said, the degree of effort involved in dung collection

and the range of uses to which it is put may vary widely: apart from fertilizer, dung may be used as fuel or building material (Moreno-García and Pimenta 2011).

Finally, domestic animals may provide less tangible resources related to their social and symbolic importance and role in exchange, e.g., as bridewealth (Russell 1998). While it would be a stretch to refer to wealth and prestige as secondary products, they may certainly be important motivations for keeping livestock and must be borne in mind when assessing husbandry practices, alongside both primary and secondary products.

Lines of Evidence for Secondary Products Exploitation

Sherratt's original argument relied heavily on artifactual, iconographic, and early textual evidence for secondary products exploitation. In Mesopotamia, Uruk-period (fourth millennium) pictographs and cylinder seals present some of the earliest representations of milking, plowing, and wheeled vehicles; in central and southeast Europe, figurines and clay models play the same role from the Chalcolithic or Bronze Age. Such representations can only ever provide a *terminus ante quem* for the origin of the activities represented, however (Chapman 1982).

Artifactual evidence is also problematic, due largely to issues of preservation. Early plows and vehicles were largely made of organic materials and are thus rarely preserved, although ard marks may provide direct evidence for the use of the former. Occasional finds in waterlogged deposits from across Europe may post-date the earliest use of the technology in any given area by centuries. For textiles, this problem is compounded by the fact that wool survives in very different conditions to plant fibers such as flax, while the associated inorganic material culture (spindle whorls and loom weights) does not unequivocally reveal which fibers were used. Nonetheless, it is notable that while flaxen fabrics are known from the Neolithic in both Europe and the Near East, woolen textile fragments start to appear in Chalcolithic and later contexts.

Neither does milking necessarily have a distinctive material culture. Perforated ceramic vessels from Linearbandkeramik (central European Early Neolithic) contexts have sometimes been linked to cheese production (Bogucki 1984), but this is by no means certain. Recent advances in stable isotope analysis of lipid residues on ceramics have allowed ruminant milk fat to be distinguished from ruminant or porcine body fat, by comparing $\delta^{13}C$ between 16- and 18-carbon chains (Evershed et al. 2008). While this technique reveals widespread use of milk from the early Neolithic in the Near East and Europe, estimating the frequency of milk consumption or its contribution to diet remains problematic.

By contrast to artifactual and iconographic data, animal bone assemblages are near-ubiquitous features of prehistoric sites, and may provide indirect evidence for the use of secondary products. Evidence for traction has been sought through systematic observation of pathologies and activity markers on animal bones (e.g., Bartosiewicz et al. 1997; Isaakidou 2006), but by far the most common approach involves quantitative analysis of age-at-death and sex ratio data (e.g., Greenfield 1988, 2005; Vigne and Helmer 2007). Systematic attempts to analyze herd management from age data began in earnest with Payne's (1973) publication of idealized mortality profiles for caprine herds managed for meat, milk, and wool, respectively (Fig. 1). Similar reasoning can be applied to cattle and their use for traction.

There are various obstacles to interpretation of mortality profiles, however. Firstly, prehistoric herds will rarely have been managed purely for a single resource, and the three models should therefore be seen as extreme cases; indeed, Payne also set out a "mixed meat and milk" profile. More nuanced models have since been proposed for "tender meat" and for nonintensive milk production more suited to primitive breeds and/or small-scale production systems ("type B milk" – Vigne and Helmer 2007). The next problem is one of equifinality: once one moves away from Payne's extreme cases, different production strategies cannot necessarily be distinguished from age data alone. Sex ratios may help to tease out different herd management strategies, although it is usually impossible to link age and sex data

Secondary Products and the "Secondary Products Revolution", Fig. 1 Idealized survival curves for sheep herds managed for meat, milk or wool, according to Payne (1973)

directly since different skeletal elements are used in each case. Widespread castration would be a strong indicator of systematic traction or wool use, in cattle and sheep respectively, but is itself difficult to demonstrate unless large numbers of intact limb bones are present.

As a result of these problems, it is not unknown for the same data to be interpreted in contradictory ways (e.g., Greenfield 2005 vs. Vigne and Helmer 2007). Moreover, particular herd structures can only ever indicate *potential* for exploitation of milk, wool, etc. (Halstead 1998). Additional factors such as herd security concerns or social incentives to maintain herds may intervene between theoretical optimal herd structures and reality. The scale of herding is important, with management of smaller herds likely to be more conservative and therefore to appear more generalist, but of course it is notoriously difficult to assess scale from bone remains. The upshot is that while highly specialized herd management might constitute convincing evidence for the type of large-scale specialized pastoralism inherent in the SPR model, the absence of such patterns does not necessarily indicate either small-scale herding or an absence of secondary products exploitation.

Matching observed mortality profiles to theoretical models is thus extremely problematic, but tracking changes over time may nonetheless help to reveal shifts in emphasis (Greenfield 2010). Post-Neolithic shifts broadly in line with the predictions of the SPR are indeed seen in the Balkans (Greenfield 2005; Isaakidou 2006), Anatolia (Arbuckle et al. 2009), and elsewhere, but their interpretation remains contentious (see Vigne and Helmer 2007; Brochier 2012).

One final line of evidence that is likely to become increasingly important in the near future is ancient DNA. On the one hand, ancient DNA studies are rapidly improving our understanding of the spread of adult lactose tolerance among human populations; on the other, genetics has the potential to trace the development and spread of traits such as woolly fleeces in sheep.

The "Secondary Products Revolution" 30 Years On

In the three decades since its inception, the SPR has been subject to critique on both empirical and conceptual grounds, and the fact that it is still a subject of debate today speaks to the contribution it made to economic prehistory. Three aspects of the model may be reevaluated in the light of recent research: (1) the idea that milking, plowing, etc., were post-Neolithic *innovations*; (2) the existence of a coherent "package" of husbandry practices that diffused from the Near East into Europe and elsewhere; and (3) the core argument for a revolution in scale and specialization of animal husbandry during the fourth millennium.

The first of these is arguably a red herring (Greenfield 2010: 46–47). While Sherratt's 1981 paper did seem to imply that the SPR involved a complex of innovations, his 1983 reprise of the model clarified that elements of this complex probably had Neolithic roots, and that the

"revolution" was one of scale. This has not prevented the construction of strawmen, however: it is hard to reconcile Sherratt's statement that "milking was probably practised in Europe by Neolithic populations" (Sherratt 1983: 95) with the view that Neolithic people were "without any abilities other than killing animals for their meat, exactly as did hunters-gatherers" – attributed to him 24 years later in an unusually passionate critique by Vigne and Helmer (2007: 35).

Regardless of Sherratt's original intentions, it is now clear that at least some features of the SPR can be traced well back into the Neolithic of Europe and the Near East. Most notably, the lipid residue evidence makes clear that milking was practiced *to some extent* from fairly early in the Neolithic (Evershed et al. 2008). Likewise, few would deny that sheep and goat fibers may have been exploited before they became fine enough to spin, or that cattle were sometimes used to pull or carry loads before the development of the ard or the wheel. On the other hand, 30 years of new empirical data has done little to overturn the idea that the plow and the wheel *were* fourth millennium developments, or that spinnable sheep's wool developed at a broadly similar time.

The second point – the idea of the SPR as a coherent package of practices that spread together – is also highly problematic. It is increasingly clear that each component had a discrete origin and subsequent take-up and spread (Greenfield 2010).

At its core, however, the SPR model was about the development of large-scale specialized pastoralism on the one hand; systematic use of cattle (and later equid) traction to transform agriculture on the other; and the implications that both had for the development of economic systems. "Large-scale" is of course an ambiguous term, but there remains considerable empirical support for the idea that major changes to this effect took place around the fourth millennium BCE in the Near East, and had taken hold in parts of Europe by at least the third millennium. The most contentious aspect of these changes is the role of milking, with debate continuing to rage over (a) whether or not the available zooarchaeological data indicate a widespread post-Neolithic shift in herd management, and (b) to what extent earlier signatures of dairying can be identified in Neolithic mortality profiles (e.g., Greenfield 2005, 2010; Vigne and Helmer 2007).

Secwepemc Cultural Education Society and Simon Fraser University (SCES-SFU) Indigenous Archaeology Program

George P. Nicholas[1] and Nola M. Markey[2,3]
[1]Department of Archaeology, Simon Fraser University, Burnaby, BC, Canada
[2]Crane Heritage, Chase, BC, Canada
[3]O-Chi-Chak-Ko-Sipi First Nation, Crane River, MB, Canada

Basic Information

The Secwepemc (or Shuswap) are an Interior Salish people of south-central British Columbia, Canada, today comprised of 17 bands. In 1989, the Secwepemc Cultural Education Society (SCES) and Simon Fraser University (SFU) entered into a partnership to develop a unique post-secondary education program for First Nations Students on the Kamloops Indian Reserve in Kamloops, British Columbia. These efforts were led by then-Skeetchestn Band chief Ronald Ignace, Marianne Boelscher Ignace (anthropologist, SFU), and Hari Sharma (sociologist, SFU). The goal was to offer university courses on the reserve in order to enhance the quality of life for the Secwepemc peoples and their indigenous neighbors; to preserve and promote their history, language, and culture; and to provide training in research and

developmental opportunities to assist them in controlling more fully their own affairs (Ignace et al. 1996). Ironically, the program started in several rooms within the former residential school run by the Catholic Church, whose mission was to "remove the Indian from the child."

The program sought to provide First Nations individuals, from near and far, with an entry into post-secondary education, but also welcomed non-indigenous students. The location on the reserve was intentional as it provided a comfortable setting distinct from that of regular universities, which many individuals found intimidating. A significant percentage of students were the first in their family to ever attend a university course or complete a university degree. The SCES-SFU program was known informally as Coyote U; the campus logo featured *Sk'elep*, the coyote, a trickster figure to Secwepemc people known for both good deeds and causing trouble.

Soon after it began, the program quickly expanded into a small campus, consisting of six portable classrooms, adjacent to the residential school. The small permanent teaching and administrative staff was complemented by sessional instructors from other academic institutions in the region. The curriculum was designed to help Secwepemc communities meet their needs, especially those related to cultural heritage. Anthropology, First Nations, linguistics, ethnobotany, archaeology, and museology were all emphasized, with courses also offered in sociology, writing, mathematics, history, and geography. Over 100 lower- and upper-level university courses were offered each year, as well as several graduate courses. Special courses and workshops were occasionally offered on treaty negotiations, film making, theater, wildlife management, and health and safety. In 1993, the SCES-SFU program received the "Award for Excellence" from the Canadian Association for University Continuing Education. The volume *Coyote U: Stories and Teachings from the Secwepemc Education Institute* (Murphy et al. 1999) is a collection of writing by students in the program.

The Archaeology program was developed in 1991 by George Nicholas (archaeologist, SFU), who directed it until 2005. The annual Archaeology Field School component combined a commitment to socially relevant, community-based archaeology with a scientific research program focused on the identification and excavation of pre-5000-year-old sites and the land-use system they represent (Nicholas 1997; Nicholas et al. 2016). These initiatives contributed to capacity building in field and research skills, as well as cultural resource management services to the communities. The Archaeology Field School (Fig. 1) provided students with a

Secwepemc Cultural Education Society and Simon Fraser University (SCES-SFU) Indigenous Archaeology Program, Fig. 1 Students in the SCES-SFU Indigenous Archaeology program received classroom instruction and field training in all aspects of archaeology – from theory and practice to community engagement. (Photo: George Nicholas)

thorough grounding in archaeological survey, site recording, testing and excavation skills, and basic laboratory analysis. The Field School worked closely with the Kamloops Indian Band to mitigate the impact of a large housing development and golf course on and around a location where Nicholas and students had previously conducted extensive field studies and conducted work on behalf of the Secwepemc Cultural Education Society and the Secwepemc Museum. These and other projects assisted the Secwepemc people in balancing current land-use plans with heritage preservation and introduced students to the very real demands of mitigative archaeology and to the rewards and frustrations that are part of cultural resource management.

Provincial certification in archaeological training was incorporated into the field school program or offered separately. The Resource Inventory Standards Committee (RISC) program prepares students with technical training in practical field methods to assist archaeologists in cultural resource management projects. This program has been delivered to numerous First Nations communities throughout British Columbia since 1997. For some, RISC training has been an introduction to the discipline of archaeology that has inspired them to pursue a post-secondary education, and for others, it has provided seasonal work. This work has provided networking with the archaeological community and other potential employers (Nicholas and Markey 2002).

The Secwepemc-SFU campus closed in 2010 due to financial cutbacks, increased competition for students, and a shift in priorities by the partnering organizations.

Major Impact

For 20 years, the SCES-SFU Indigenous Archaeology Program provided archaeological courses and field training to hundreds of First Nations students, more than any other institution in Canada. It created opportunities for their involvement in stewardship, heritage management, heritage policy making, developing on-reserve permit systems, cultural sensitivity in heritage research, land-use planning, cultural liaison with industry, and even mentoring for high school students. Through its archaeology, ethnobotany, and language immersion courses, the SCES-SFU campus offered many opportunities for First Nations students to visit, or revisit, parts of their traditional territories and to work with elders who as teachers and cultural advisors introduced them to knowledge lost to the language and cultural restrictions imposed through the residential school system and earlier Federal Indian policies.

For its part, archaeology assisted community members in identifying more fully with their culture by supplementing and expanding oral histories and by giving them the tools to identify, recover, and interpret ancestral sites and the material culture contained therein. SCES-SFU students have subsequently pursued their interests in heritage in a variety of contexts, including:

- As band council or committee members charged with making decisions on land-use planning (including archaeological overview assessments) for their communities
- As archaeological permit holders, project managers, business managers, project directors, or crew members for cultural resource management companies working on local, national, and international projects
- As managers, researchers, and field workers within First Nations cultural and/or natural resource departments, involved in archaeological and environmental assessments that incorporate both western science and traditional knowledge
- As museum archivists and tour guides
- As graduate students having the opportunity to teach at universities as sessional instructors
- As educators and instructors who have incorporated archaeology, ethnobotany, and language into the curriculum into elementary, high school, and university-level courses

The SCES-SFU program represented a manifestation of Indigenous Archaeology in which First Nations' concerns with heritage were addressed by providing First Nations members with the tools of archaeology that they could employ themselves as CRM practitioners, educators, or decision-makers. The approach melded community values and

recognition of sensitive and sacred places with scientific collection and preservation of archaeological materials and has proved pivotal in educating future generations of both First Nations and the general public about First Nations histories, cultural identity, political perspectives, and social dynamics. It has also served to enlighten the industry (private and corporate) and government with respect to developing better relations and protocols with First Nations (Markey 2010). The program has left a lasting legacy in Secwepemc territory, as well as contributed to the increased breadth of archaeological practice elsewhere.

Seeds: Conservation and Preservation

Patti J. Wright
Department of Anthropology, Sociology, and Languages, University of Missouri-St. Louis, St. Louis, MO, USA

Introduction

Not all seeds that are preserved and recovered from archaeological contexts reflect uses by past peoples. Some of the seeds may be of modern origin: they may have been blown in, dropped from local plants (i.e., "seed rain"), or transported by burrowing animals or plant roots. Seed rain

also operated in the past and could be a source during site occupation and after site abandonment. At mesic sites where, as discussed below, carbonization is normally deemed necessary for preservation, uncharred seeds are often considered modern intrusions. However, the burning of an abandoned occupation site may result in the deposition of considerable quantities of carbonized seeds incidentally introduced by seed rain. Carbonized seeds can also be a result of indirect sources such as burning dung for fuel (Miller and Smart 1984). At water-logged sites, seeds may be introduced via beach drift (Matthews and Gosden 1997). Understanding depositional history is thus critical to interpreting seeds that have been preserved and recovered from archaeological sites.

Definition

Seeds are plant reproductive structures. In flowering plants, they develop within ovaries, and the ovaries and seeds then develop into fruits. The term "seed" as applied in many archaeological contexts refers to true seeds as well as kernels, achenes, pits, pips, and other kinds of dry fruits. It was the recovery of ancient seeds among other floral remains by nineteenth century researchers like John Harshberger, Oswald Heer, and Carl Kunth which propelled interest in the uses of plants by past societies. By the mid-twentieth century, it became widely recognized that seeds derived from archaeological deposits provide the kind of data needed to answer questions about diet, origins of food production, diffusion of cultigens, biodiversity, land use strategies, medicinal and ritual practices, and technological use of plants.

Key Issues/Current Debates/Future Directions/Examples

There are a number of means by which seeds may survive physical and chemical decomposition to become a part of the archaeological record. These include carbonization, desiccation, quick-freezing, and water-logging. In general, these processes inhibit the growth of decomposers like bacteria or saprophytic fungi, slow the rate of enzyme action, and lower the speed at which chemical reactions occur (Sobilik 2003: 21–28). Desiccation, quick-freezing, and water-logging are remarkable for the types of tissue preserved, if not for the shear abundance of material. The water-logged deposits of the ancient lake dwellers who built wooden houses along the shores of Switzerland's lakes have yielded cultivated grains, fleshy fruits, field weeds, legumes, and nuts, among many other kinds of plant remains, whereas the dry coastal valleys of southern Peru are equally rich in yielding desiccated seeds. Unfortunately, preservation by these means is relatively rare.

Most seeds are derived from open-air archaeological sites in mesic habitats where supplies of moisture are moderate. There the botanical remains are often subjected to oscillations between wet and dry regimes that increase their susceptibility to chemical decomposition. Repeated cycles of wetting and drying bring the seeds into contact with fresh supplies of inorganic and organic acids and bases (Bryant 1989). These substances dissolve or weaken cellulose (a component of most plant cells) to such a degree as to accelerate mechanical reduction. Also, a host of small organisms that facilitate decomposition inhabit mesic environments. Dead plant materials serve as food for earthworms, millipedes, ants, and mites, among other soil organisms (Bryant 1989). Fungi and bacteria, nature's most effective decomposers, also abound. Under these conditions, dead organic matter tends to decay rather rapidly. There are exceptions. First, seeds that were deeply and quickly buried may preserve. Deep layers of silt or clay can result in relatively anaerobic conditions that inhibit saprophytic organisms. The deeper the material is buried, the better the potential for preservation (Sobilik 2003). Such situations can arise in the case of a mudslide or in the event of the quick burial beneath meters of mound fill.

The second and a major exception are those seeds that have undergone the physical and chemical changes associated with carbonization. During the carbonization process, chemical constituents

are converted to elemental carbon, which is extremely durable and offers no nutrients on which saprophytic organisms can feed (Sobilik 2003). Beck (1989) developed and conducted experiments to evaluate basic rates of decomposition for carbonized and non-carbonized remains. She found that rates of decomposition will be greatest at those sites where the sediments are warmer, wetter, have higher organic carbon content, are more alkaline, and have more concentrated soil nutrients (e.g., phosphorus, calcium, nitrogen). However, if a seed is composed of more resistant materials – it has been carbonized – such a state will outweigh environmental factors. In many cases, seeds that have fortuitously carbonized can withstand the rigors of mesic environments.

While carbonization is a mechanism by which seeds can preserve, it is a very biasing mechanism (Wright 2003). Carbonized seed assemblages tend to reflect only a small portion of the population of plants used by past peoples. Miksicek (1987) illustrated this point when he observed traditional saguaro fruit harvesting and processing by members of the Tohono O'odham, and a year later returned to sample the processing loci. Ultimately, he found that "The flotation samples yielded evidence for approximately 0.2% of a morning's work, of which only 0.02% was carbonized" (Miksicek 1987: 221–222). Carbonization, hence the likelihood of seed preservation in mesic contexts, is influenced by proximity to a heat source which, in turn, is influenced by how seeds were used and/or discarded. For example, seeds consumed as a part of eating a fleshy fruit would have less of a chance to be introduced to a heat source and carbonize, than the accidental burning of maize kernels while roasting an ear or the partially digested grains contained within animal dung that was burned as fuel.

The culturally dependent phenomenon of proximity represents only a portion of the preservation equation. The ability of plant materials to carbonize is dependent on phenomena such as thermal intensity, length of exposure, the presence of oxygen, and moisture and chemical contents. A number of researchers have experimented with the carbonization process (for examples, see Wilson 1984; Wright 2003; Margaritis and Jones 2006; Braadbaart et al. 2007; Markel and Rosch 2007). Wilson (1984) and Wright (2003) observed that a particular seed accidentally subjected to a high temperature for a very short time may differ in distortions or degree of degradation than one exposed to a lower temperature for a longer time. Markel and Rosch (2007) and Wright (2003, 2008) noticed differences in the survival of oily versus starchy seeds: oily seeds may have less of a chance of fully carbonizing at lower temperatures than their starchy counterparts. Carbonization can impact the shape and dimensions. For example, Wilson (1984) and Wright (2003) found that there is less size change in drier seeds than in moisture specimens. The potential impact on size has ramification when researchers rely on lengths, widths, and diameters of seeds to determine if a plant remain reflects a wild or a domesticated species (see Braadbaart and Wright 2007).

Carbonization and postdepositional processes can reduce seeds and fruits to simpler structures, as seed coats, embryos, and endosperm are disarticulated (Pearsall 2000). Mechanical damage due to a host of natural activities such as freezing and thawing, gravity, rodent gnawing, and so on can thoroughly destroy seeds or render them unidentifiable. Seed coats, which are often an important to identification, can be lost, blackened during carbonization, highly eroded when desiccated, and distorted or lost in the event of water-logging (Pearsall 2000). Even the methods used to recover the seeds can impact whether or not the seed will be preserved in an identifiable state as a part of the archaeological record as the wetting of remains during flotation can cause increased splitting and damage seeds that will impact recovery rates (Wright 2005).

Seeds recovered from archaeological sites as well as the associated documentation (e.g., analytical forms, reports, images, and so on) need to be conserved for future reference. Unfortunately, little has been written in the archaeological literature about this topic. Conservation of archaeological remains recovered from marine contexts is perhaps the most researched and published in the archaeological literature. One of the more crucial tasks is the removal of salts from any seeds or other plant materials excavated from salt-water deposits. The

Conservation Research Laboratory at Texas A&M University provides details about how to conserve all kinds of archaeological remains recovered from such contexts (see http://nautarch.tamu.edu/CRL/conservationmanual/File1.htm).

Governments, museums, and other professional organizations provide guidelines for conserving organic materials. For example, the U.S. Department of the Interior, National Park Service provides free, online leaflets, referred to as "Conserve O Grams," that treat preservation issues of all kinds of remains including organic materials like seeds. Phenomena to avoid when storing seeds include excessive heat, direct sunlight, radical changes in temperature and humidity, atmospheric pollutants, and pests as all of these can be deleterious. Collections should be regularly inspected to detect and record deterioration of the seeds themselves or of associated labels, containers, and/or archival documents. Also appropriate are procedures used by herbaria. Courses like that offered by the Brooklyn Botanic Garden in conjunction with the Royal Botanic Gardens, Kew, where international and institutional standards of curating plant materials at herbaria and ideas about promoting collections of plant materials to scientific and lay communities are discussed, can be useful sources of information in the curation and conservation of archaeologically recovered seeds.

Seleucid, Parthian Mesopotamia, and Iran, Archaeology of

Roberta Menegazzi
Centro Ricerche Archeologiche e Scavi di Torino per il Medio Oriente e l'Asia, Torino, Italy

State of Knowledge and Current Debates

At the time of Alexander's conquest, Iran and Mesopotamia, which were regions of ancient civilization possessing a multi-millenary history of contacts, exchanges, and conflicts, had been part of the Achaemenid Empire for two centuries. With the conquest of Babylon by Cyrus the Great in 539 BCE, Mesopotamia lost its political independence, becoming part of a multinational empire that had its center in Iran, homeland of the ruling dynasty. Nevertheless, thanks to its key geographical position and to its rich agricultural resources the region still played a very important role within the empire. The city of Babylon enjoyed a privileged status and was one of the royal residences of the Achaemenid kings, together with Pasargadae-Persepolis, Susa, and Ecbatana.

In choosing Babylon as the capital city of his empire, Alexander shifted the axis of the political power from Iran to Mesopotamia. A few years later, in 311 BCE, Alexander's general Seleucus – satrap of Babylonia from 320 to 315 BCE – moved from Babylon with the aim of conquering what was going to be the largest of the Diadochi kingdoms, first annexing Media and Susiana. The centrality of the area was confirmed by the Arsacids, the Iranian dynasty that succeeded the Seleucids in the rule of the Asian Alexander's heritage. They set up their capital in Ctesiphon, which was opposite the Greek metropolis of Seleucia on the Tigris. Ctesiphon also retained its role as capital under the Sasanians, who displaced the Arsacids in the early third century CE.

From the Achaemenid time on, the political destinies of Mesopotamia and Iran were closely linked: for over a millennium, they were part of complex state structures, characterized by the coexistence and – with different nuances depending on different periods – by the transmission and assimilation of artistic and cultural features of various origins. It was the conquest of the Persian Empire by Alexander the Great that especially opened the Near Eastern and Central Asian territories to Greek culture and led to an extraordinary process of encounter and exchange with the local cultures. The available archaeological data enable one to recognize the significance of this process and to observe some of its results, but unfortunately it does not enable one to follow step by step every single phase of it. Because of their political and cultural centrality, Iran and Mesopotamia must have played a key role in the intercultural dialogue between the Greek culture, the Iranian element, and local traditions; in spite of this, the archaeological documentation coming from these areas is far from being complete.

The Seleucid Period

The archaeological documentation from the Seleucid period is particularly scanty. In the case of Mesopotamia, the lack of data is at least partly due to the difficult political situation suffered by Iraq in the last decades, which has resulted in a necessary reduction if not an almost complete lull in the field activities. This situation has been partly counterbalanced by recent developments in historical research that has offered a more articulated picture of the administrative, social, and economic reality of the Seleucid Empire through its growing attention to the local sources.

In spite of the systematic investigation conducted during the last century on the site of Seleucia on the Tigris, the Seleucid court art and architecture still remain unknown. In fact, 20 archaeological campaigns carried out during the last century by the University of Michigan and the Centro Ricerche Archeologiche e Scavi di Torino per il Medio Oriente e l'Asia only affected a very small portion of the entire surface of the city, which encompasses a surface of about 550 ha on the right bank of the Tigris, approximately 30 km south of Baghdad. Moreover, the Seleucid levels were reached only in some of the investigated areas. Seleucia was founded in the last years of the fourth century BCE by Seleucus I; its location – close to the mouth of the Royal Canal and the outlet of the Diyala Valley – was highly strategic for the communications between the western territories and the far eastern lands of the empire via the Iranian plateau. The city master plan probably falls under the foundation period (Fig. 1). The urban layout was organized in accordance with basically Greek planning principles: the main public buildings are concentrated in the northern part of the city, where wide open areas divide the regular grid of rectangular blocks. These are the largest in the Hellenistic world, with an extension of 144.70 × 72.35 meters, and they are bound by streets intersecting at right angles. A larger east-west street running along the southern limit of the urban perimeter and a ship canal cutting it in two halves are the main street axes. On the northern limits stood the theatre, a major institution in a Greek city. The massive remains of its mud-brick substructures, enclosed later in a Sasanian watchtower, form the artificial mound of Tell 'Umar that dominates the archaeological area of the city. Immediately south of the theatre, the agora is an open area with a long, rectangular shape. On the east wing of the square stands a stoa; the west wing is occupied by the public archives, hosted in a building destroyed by fire in the last quarter of the second century BCE and never rebuilt.

The Greek character of Seleucia on the Tigris is hardly surprising. The city was a royal Macedonian foundation, and it was conceived as the eastern capital of the Seleucid Empire. What is remarkable is the ability for Macedonians to adapt Greek features to a different geographic and cultural context, as shown by the huge size of the city, by the presence of a ship canal as a main street axis or by the use of mud-brick for the civic theatre. Moreover, some data point to the coexistence of different architectural traditions: in the agora, a stoa, an edifice with a strictly codified Greek plan, is opposite a building that hosted archives and whose plan offers analogies

Seleucid, Parthian Mesopotamia, and Iran, Archaeology of, Fig. 1 Seleucia on the Tigris. Schematic plan of the city (Archive Centro Scavi Torino)

S

with Mesopotamian temple precincts (Messina 2007: 60–63). Also the seal impressions found inside the archival building testify to the complex cultural life of Seleucia. Over 11,000 figured seals offer an overview of the different features of artistic production that existed in the Seleucid period. Hellenistic style and iconography predominate: particularly noteworthy are the large set of representations of Greek gods and the portraits of the Seleucid kings, some of which are true masterpieces of the Hellenistic glyptic (Fig. 2). Besides Greek subjects one can still find a little but significant number of pre-Hellenistic patterns, both of Mesopotamian and Greco-Persian origin: priests with conical cap, composite beings, hunting scenes, pig-tailed figures (Invernizzi 2004).

The coexistence – in different proportions – of Greek and local elements appears to be a common feature of the main cities of Seleucid Mesopotamia. With the foundation of Seleucia on the Tigris, Babylon lost its dominant position in terms of internal and international politics. However, it was still an important regional center, as testified by written sources and archaeological remains. The first phases of the theatre, which is located in the northeastern sector of the city known as Homera, may have dated to the last years of the fourth century BCE. The mud-brick cavea leans on an artificial mound formed by debris coming from other areas of the city. The presence of a theatre fits well within the framework of the city, whose Greek community was organized as a polis. On the other hand, textual documents and archaeological data both attest continuities in the use of pre-Hellenistic buildings, from the royal palaces to the temples. Several texts record Seleucid royal activities – restoration works and offerings – in Esagila, the sanctuary of Marduk. Similarly, the enclosure walls of the ziggurat Etemenanki show traces of Seleucid works. The active role of the Seleucid kings in the religious life of the main Mesopotamian centers – which is clearly testified by the well-known cylinder of Antiochus I from Borsippa, the last known royal inscription written in cuneiform, celebrating the restoration of the Ezida temple – coheres completely with the political attitude of the new rulers. These were respectful to the different cultures of their composite empire inasmuch as they were particularly concerned with the accomplishment of the duties connected to Babylonian kingship.

Seleucid, Parthian Mesopotamia, and Iran, Archaeology of, Fig. 2 Seleucia on the Tigris. Clay sealing with portrait of the Seleucid king Demetrius II. (Photo archive Centro Scavi Torino)

The continuity of traditional religious practices is even more evident in the case of Uruk, the most ancient center of Southern Mesopotamia. Texts of Seleucid period mention the "High Akitu of Anu" and the "Akitu of Ishtar," attesting that at Uruk, the celebration of the New Year festival continued to be performed during the Seleucid times. The main temple complexes of the city – the Bit Resh and the Irigal – were constructed and renovated according to the traditions of Babylonian religious architecture, both in terms of plan and decoration. Both sanctuaries were built on a Babylonian court plan; the temple proper was set in a walled precinct that included several courtyards lined by rooms, chapels, and passages. The outer walls of the temples and, in the case of the Bit Resh, more extensively investigated, the sides of the main courts of the whole precinct were decorated with projections and niches in the traditional Mesopotamian style. Archaeological and textual evidence show that in Seleucid times, the Bit Resh was the

most important religious complex in Uruk. The sacred precinct and the associated ziggurat were dedicated to the sky god Anu, who replaced Inanna-Ishtar as the preeminent deity of the city, and to his wife Antum. The Irigal became the main temple dedicated to the worship of Ishtar and Nana, thus superseding the ancient E-anna temple, which still remained in use until late Seleucid to early Parthian period. In charge of the works in the Bit Resh was the governor of Uruk, a member of the Anu-uballit family who received the Greek name of Nikarchos from the king Antiochus II. Subsequent works were undertaken by another member of the family, Anu-uballit Kephalon, governor of the city under Antiochus III (Downey 1988: 15–35). The fact that the local ruling elite was closely connected to the royal dynasty is testified by the royal practice of conferring Greek names on its members; moreover, such important works as the ones carried on in the Bit Resh sanctuary had to enjoy direct or indirect royal patronage. Even Uruk, in spite of its strongly conservative character, shows important traces of Greek cultural presence, testified by the exceptional discovery of the two tumuli of Frehat en-Nufegi. Both tumuli, located north of the city, had a burial chamber with corbelled vault. The western tumulus hosted the burned remains of four adults, buried in four urns; the eastern one was the burial place of a single adult, originally lying on a kline. In this case, both the funerary practices and the grave goods – which include golden wreaths and iron strigils – are completely foreign to the Mesopotamian milieu and point to the Greco-Macedonian world (Pedde 1991).

If we look at the material culture, the relation between Greek and Mesopotamian tradition seems to go beyond the simple coexistence of features of different origins. In the case of the pottery production, the extremely rich documentation shows that already in the Seleucid period Mesopotamian craftsmen freely employed the local technique of the alkaline glazing to produce vessels highly inspired by western prototypes such as the so-called fish plates, extremely popular in the Mesopotamian area during the Seleucid period and attested until fully Parthian times (Valtz 1993: 170–172). Unfortunately, the thousands of terracotta figurines found in Central and Southern Mesopotamia do not provide precise indications on the first phases of the encounter between Greek and Mesopotamian traditions: examples certainly dating to the Seleucid period are too rare to be informative about the tendencies of the coroplastic production of that époque. Some representations of gods on the seal impressions from Seleucia on the Tigris stand out in that respect, for their western iconography is enriched with Mesopotamian features that allow one to offer a twofold Greco-Mesopotamian interpretation: Athena-Nanaia-Artemis with a helmet, crescent, and torch and Apollo-Nabu with an arrow stylus in the hand and a crescent and tablet in the field (Invernizzi 2004).

Archaeological data coming from Northern Mesopotamia are very scanty and seem to suggest a contraction of the settlements in the area. At Nimrud, traces of a third- or second-century village were found in the area of the Ezida temple. At Nineveh, surface pottery finds that can be closely compared with the materials from Nimrud possibly indicate a Hellenistic occupation of the area east of the citadel. Besides, some epigraphic evidence point to a potential Seleucid origin as regards the organization of the city as a polis (Reade 1998).

French excavations carried out since 1986 at Dura Europos, a Macedonian foundation on the northwestern corner of Mesopotamia, shed new light on the early history of the site. The city, with its Hippodamian plan and its powerful fortifications, is now dated to the latest phases of Seleucid rule, around the middle of the second century BCE. In early Seleucid times, the site was only the place of a stronghold established on a citadel in order to control the route connecting the two capital cities of the empire, Antiochia on the Orontes and Seleucia on the Tigris (Leriche 2010). Beyond the southern limits of Mesopotamia, the island of Failaka, near the head of the Gulf, was the seat of a small Hellenistic settlement dating from the end of the fourth to the second century BCE. Both the material finds from the excavations – namely, the pottery and the terracotta figurines – and the epigraphic

evidence point to the coexistence and mutual exchanges of Greek and non-Greek elements (Salles 1993).

The archaeological data from Mesopotamia allow one to recognize some of the cultural dynamics generated by the encounter of Greek culture and local traditions; by contrast, the information coming from Iran is too fragmentary to enable the creation of a general interpretive framework. The historical sources attest the interest of the Seleucid rulers in Iran. As already mentioned, in 311 BCE, Seleucus I started to build his empire by annexing Media and Susiana. Moreover, Seleucid rule in Iran was consolidated by new foundations, by the refounding of old cities and by the establishment of garrison sites. Unfortunately, the pattern of the Seleucid settlements in Iran has largely been lost, and many of the foundations quoted by the written sources have not yet been identified on the ground. The archaeological remains of the Seleucid period are not homogeneously distributed on the Iranian plateau; on the contrary, they are mainly concentrated in the western regions, namely, Media and Susiana, which were areas of great economical and strategic importance for the ruling dynasty. In the heart of Media, close to Nahavand, the Greek city of Laodicea was founded. A stele found on the site bears a double Greek inscription – dated to the reign of Antiochus III – that identifies the city as a Greek polis and testifies to the spread of the Seleucid dynastic cult in Iran. At Bisutun, on the route connecting Mesopotamia to the Upper Satrapies, there was a Greek sanctuary dedicated to Heracles. To the sanctuary belonged the well-known high relief depicting the reclining hero, with an inscription dated to 148 BCE. Further north, in Media Atropatene, a Seleucid garrison was established on the site known as the Karafto Caves (Kuhrt and Sherwin-White 1993: 72–81).

The city of Susa was refounded as a Greek polis under the name of Seleucia on the Eulaios. Not much data concerning its Seleucid phases are available. The site was an object of systematic exploration by French archaeologists from the end of the nineteenth century on, but the documentation concerning the recent phases suffered neglect from the lack of interest of the first archaeological missions. A recent reexamination of the data collected in almost a century of excavations has led to the conclusion that the city was not densely populated in the early Seleucid period. The Greek presence became more manifest starting from the second half of the third century BCE. In the meantime the city underwent a strong commercial development that reached its peak in the period between the end of Seleucid times and the first century CE (Martinez-Sève 2002a). From the excavations of Susa come many terracotta figurines – generically dated to the Seleucid-Parthian period – whose iconography and style testify to the contemporary presence of Greek and Near-Eastern influences. The presence of types from the coroplastic repertoire of Susa – namely, naked female figures and riders – in other sites of Susiana and Elymais testifies to the cultural influence exercised by the city between the Seleucid and the Parthian periods (Martinez-Sève 2002b). A fragment of a bronze statue possibly depicting a Seleucid king found in the sanctuary of Shami, in Elymais, suggests that the sacred area was already in use in the Seleucid period.

In Fars, homeland of the Achaemenid dynasty, the Achaemenid heritage has been evident for a long time, and the reuse of previous buildings was a common practice: at Pasargadae, the archaeological data point to continuity between the Achaemenid and the Seleucid phases. The interest of the new ruling dynasty in the area is evident in the foundation, probably by Antiochus I, of the city of Antiochia Persis, whose localization on the ground is still debated. Fragments of marble statues of Hellenistic taste – some of which are considered to be imports from the Eastern Mediterranean – were found in different sites of the region (Callieri 2007). On the whole, the number and variety of the archaeological remains support scholars' quite recent reassessment of the end of the Seleucid rule in Fars. On the basis of the coins minted by the first local rulers, the *frataraka*, the end of the Macedonian control of the region has been shifted from the beginning of the third to the beginning of the second century BCE.

The Parthian Period

141 BCE marks the beginning of Parthian rule in Mesopotamia. This was when the city of Seleucia on the Tigris was taken by Mithridates I, founder of the Arsacid Empire. The attempts of the Seleucid king Demetrius II and his successor Antiochus VII to regain possession of Mesopotamia were in vain and ended with the defeat and death of Antiochus VII in 129 BCE. During the reign of Mithridates II (123–88 BCE.), who expanded the empire, Parthian rule stretched from Central Asia to the Euphrates.

The starting point for the conquests of Mithridates I was Parthia, a region of outer Iran that had been under Arsacid control since the second half of the third century BCE. In Parthia, at the feet of Kopet Dagh mountains, Mithridates I founded Old Nisa/Mithradatkert: not an ordinary seat of the Arsacids, but the center of their dynastic cult. The site is of a primary importance: from Nisa comes the only available evidence of Arsacid court art and architecture, as the royal residences of the Parthian rulers have been so far unknown; the Parthian levels of Ctesiphon have not yet been located on the ground, and the excavations at Shahr-i Qumis near Damghan, which has been identified with Hecatompylos, the former capital of the Parthian Empire, did not bring to light any evidence related to palatial architecture. The ceremonial buildings unearthed in Old Nisa by Soviet, Russian, and Italian excavations (Pilipko 2001; Invernizzi and Lippolis 2008) conform to the Iranian architectural traditions of Central Asia in their recurring use of centric layouts organized around a central space surrounded by perimetral rooms and/or corridors. Moreover, two of the buildings of the central complex – namely, the Red Building and the Tower-Building – are characterized by the presence of facade porticoes (Fig. 3). The most recent excavations have demonstrated that the main ceremonial buildings of Nisa – not only the Square House, but also the central complex – were flanked by large built areas used for stocking and storing food. As highlighted by the excavator, the association of religious/ceremonial buildings with administrative/economic structures conforms to an ancient eastern tradition (Lippolis 2013: 114). The architectural decoration features patterns of Greek origin that have been freely adapted to the different exigencies of mud-brick architecture; this is the case, for instance, with the terracotta-assembled capitals. The influence of Hellenistic culture is definitely stronger in the works of art. If the marble statuettes and some of the metal figurines are purely Hellenistic works (Invernizzi 2000, 2009), the monumental clay statues – unfortunately badly fragmentary – possess western features that find expression in a technique which is meant for great fortune in Central Asia, as demonstrated by Kushan and Greco-Buddhist clay sculptures (Fig. 4). The 48 ivory rhytons found in the Square House are the extraordinary result of a synthesis of Greek subjects, Iranian elements, and local tastes and traditions (Fig. 5). The drinking horn, a type of vessel widespread in Iran and Central Asia, is enriched with a decorative apparatus dominated by clearly western themes and iconographies such as, among the others, the twelve Olympian gods, the twelve labors of Heracles, and the members of the Dionysian cortege that decorate its upper frieze (Pappalardo 2010). All of the Nisean finds contribute to underlining both the philhellenism of the first Arsacid kings and the ability of local artists to re-elaborate cultural influences of different origins. In fact, the synthesis of Greek, Iranian, and local traditions is a common trait of much of the archaeological evidence from the Parthian period.

Greek culture still maintained a considerable influence at Seleucia on the Tigris. Under the new rulers, the city kept flourishing through its commercial activities and retained a high degree of political and administrative autonomy. This status, however, changed after a revolt of the Seleucian inhabitants in the first century CE. The Arsacid kings were aware of the strategic importance of the site: opposite Seleucia, on the left bank of the Tigris, they founded Ctesiphon, capital of the empire from the first century CE, whose Parthian phases have not yet been identified on the ground. In the area of Seleucia-Ctesiphon – named by the Arabic sources al-Madā´in, "the

Seleucid, Parthian Mesopotamia, and Iran, Archaeology of, Fig. 3 Old Nisa. Schematic plan of the central complex. (archive Centro Scavi Torino)

cities" – urban settlements flourished up to the Islamic period.

The development of Seleucia on the Tigris in Parthian times respects the outline of the Seleucid layout. Important public buildings, such as the theatre, are maintained. By contrast, in the agora dwelling houses and workshops are built on the remains of the archival building and the stoa. At the southern limit of the city, a large commercial square not foreseen in the original plan is opened, facing the above-quoted main east-west street. The excavation of a dwelling block in the southern half of the city illuminates the emergence, between the first and the second century CE, of a new architectural feature that characterizes civil and religious Mesopotamian architecture of the first century CE: the iwan, a large rectangular room open on one short side (Hopkins 1972). According to the excavators, at Seleucia the evolution in the domestic architecture is contemporaneous to the introduction of stucco in the architectural decoration of the block. The

coroplastic repertoire from Seleucia gives us a reflection of what probably was the richness of the artistic production of the city. Over 11,000 terracotta figurines brought to light by excavations are the product of a sustained process of interaction and synthesis between Greek and Mesopotamian culture. New western iconographies, styles, and techniques of manufacturing stimulated the renewal of practices that had persisted for millennia. Ancient Mesopotamian subjects, such as rigidly standing nude women, nursing women, musicians, riders, animals, and scale models, coexisted with western subjects, such as Greek deities, women in Greek dresses, reclining figures, children, grotesques, and theatrical masks (Fig. 6). At Seleucia, Greek and Near-Eastern iconographies did not form distinct clusters and were not free from reciprocal influences. Quite the opposite, their reciprocal contacts resulted in a

Seleucid, Parthian Mesopotamia, and Iran, Archaeology of, Fig. 7 Babylon. Plan of the theatre (Graphic elaboration Claudio Fossati)

profound transformation of both traditions and led to the creation of a new and original iconographic and formal language. From Seleucia on the Tigris, such a language spread throughout the lands of Babylonia, as testified by the presence of types originated in Seleucia within the coroplastic repertoires of Babylon, Nippur, Uruk, and minor sites of Central and Southern Mesopotamia (Menegazzi 2014: 59–63).

Continuity with the Seleucid phases and the strength of local traditions, together with the intensity of intercultural dialogue and the creation of new artistic solutions, are features that Parthian Seleucia shares with the other regional centers. The persistence of ancient local customs is demonstrated by the burial practices. Even though extramural cemeteries are attested, intramural burials appear to have been the norm, both in inhabited dwelling houses and in abandoned areas of the city. Various types of inhumation included simple ditch graves, jar burials, backed brick graves, and vaulted tombs with loculi. Glazed ceramic "slipper coffins" were a particularly distinctive type that was popular in Central and Southern Mesopotamia during the first to second century CE.

The urban layout of Babylon shows elements of continuity with the previous phases. The theatre remained in use until the second century CE; it was accompanied by an adjacent peristyled building variously interpreted as a gymnasium or an agora (Fig. 7). In the Merkes, an area whose occupation goes back without interruption to the neo-Babylonian times, the Parthian houses follow the same plans already in use in the Seleucid period; they are characterized by a peristyled courtyard. On the contrary, during the Parthian period, the big sanctuaries were progressively abandoned. At Babylon, there is no archaeological evidence showing continuity in the use of the Esagila, even though some texts indicate that the sanctuary was still in use in the early Parthian period. A cuneiform tablet from Uruk dating to 108 BCE demonstrates that the Bit Resh and the Irigal were in use at that time. However, both sanctuaries were destroyed by fire during the first century CE, and dwelling areas were situated on their remains. At Uruk the temple of Gareus, located on a mound to the southeast of the Bit Resh and Irigal sanctuaries, provides a sample of the religious architecture of Parthian period. Its interior follows a plan of Babylonian type, with a

forecella and a cella of equal breadth. By contrast, the decoration of its outer walls freely employs architectural details of clear western influence, such as fluted engaged columns with Ionic bases and Ionizing capitals. The temple was made of baked brick; stucco was employed in its architectural decorations, for molding the flutes of the columns and for the finishing details of the decorated bricks.

The original synthesis of different cultural influxes shown by the temple of Gareus is a common feature of many architectural remains from Northern Mesopotamia. During the Parthian period, this area experienced great development, as testified by the growth of urban settlements. Parthian-era Assur covered more or less the same extent of the ancient city, and this old Assyrian capital has provided substantial architectural evidence for continuity and expansion. The persistence of old religious practices is testified by the rebuilding of the Bit Akitu on its old plan. On the contrary, the so-called peripteros is a combination of very different features: the nucleus, which consists of a broad forecella and cella of Babylonian origin, is preceded by an *iwan* on the façade and a peristyle that surrounds the back and the sides of the building. Likewise, a multiple *iwan* temple is built on the ruins of the old Assur temple. This peculiar feature also recurs in residential architecture, as shown by the palace of Assur: a large *iwan* opens to each side of its central courtyard. The stuccoed decoration of the courtyard's façades was organized in three registers of slender engaged columns that framed niches.

Many of the features evidenced for Assur recur in the architecture of Hatra, the main center of the Jazira. Located on a frontier zone between the Parthian and Roman empires, the city was governed by Arab rulers while being under the Parthian political sphere of influence. The archaeological data elucidate its extraordinary development in the late Parthian period, between the second and the first half of the third century CE. The heart of the city was the sanctuary dedicated to the sun god Shamash, and this sacred precinct enclosed many temples. Whereas the temple of Maran – rising on a high podium and surrounded by a double peristyle – recalls Romanized Syrian temples, the *iwan* is the dominant feature of almost all the temples built on the western part of the *temenos*. Particularly outstanding is the "Great Iwans" complex, a series of juxtaposed *iwans* with a number of subsidiary rooms. Its façade, 115 meters long, is dominated by arched openings, framed by richly sculpted archivolts and separated by high engaged columns (Fig. 8). On the contrary, some of the small shrines built outside the sacred precinct, in the dwelling areas, show plans analogous to earlier Mesopotamian religious architecture.

Besides architecture, the city of Hatra has left us a large body of evidence for figurative arts. These include reliefs and statues depicting gods and members of the city elite involved in ritual acts or in devotional attitude. These sculptures are characterized by the strict frontality of the poses, the descriptive taste in the careful rendering of decorative details and the paratactic organization of the figured scenes. In his essay *Dura and the Problem of Parthian Art*, which was focused on the figurative documents from Dura Europos and was published in 1935, Michael Rostovtzeff identified these features as main principles of Parthian art. Thanks to the availability of further artistic evidence from the Parthian world, today we can say that the abovementioned principles, rather than the art of Parthian times as a whole, define an artistic tendency that developed in the late Parthian period; has been attested in different areas, namely, Northern Mesopotamia and Elymais; and spread even beyond the geographical and chronological limits of the Parthian Empire. In fact, Palmyra – whose figurative production share common traits with the Durean and Hatrean art – falls within the Roman cultural and politic sphere of influence, and many of the mural paintings from Dura Europos are dated after the Roman conquest of the city. Moreover, some artefacts from Northern Mesopotamia seem to suggest the contemporary presence of different artistic tendencies, even in the same area: this is the case of the statuette of Heracles Epitrapezios from Nineveh, which dates to the second century CE and was strongly inspired by western models (Invernizzi 1989). As regards Central Mesopotamia, the terracotta figurines found in the most

Seleucid, Parthian Mesopotamia, and Iran, Archaeology of, Fig. 8 Hatra. The Great Iwan complex from southeast, detail. (Photo Antonio Invernizzi)

recent levels of Seleucia on the Tigris similarly testify to the coexistence, in the coroplastic repertoire of late Parthian times, of different stylistic tendencies, as the same iconographic types were produced both in a very simplified and in a more naturalistic style (Menegazzi 2014: 33–34). In the light of that complexity, a recent essay has pointed out the necessity of a diachronic re-reading of the figurative materials of the Parthian period in order to trace a history of Parthian art (Invernizzi 2011).

Similar complexity also characterizes the Iranian archaeological remains. The culture of Iran in the Parthian period is marked by strong regional features and significant gaps in the archaeological documentation. It is nonetheless possible to recognize some of the cultural traits already highlighted within the Mesopotamian context.

The strength and variety of local traditions are verified by the different burial practices attested in the various areas of Iran: jar burials in the north, rock tombs in Media, cairn burials in Fars and in the southeast, and vaulted tombs at Susa. In regard to the architectural remains, the temples built on the sacred terraces of Bard-e Neshandeh and Masjid-i Sulaiman, in Elymais, are indebted to Iranian and Near-Eastern building traditions. Particularly, the temple of Bard-e Neshandeh – with its portico on the façade and the central, four-columned room surrounded by shallow, rectangular spaces – perfectly fits with the Iranian and Central Asian architectural traditions already mentioned for Old Nisa. Features of Iranian origin – the portico and the circumambulatory corridor isolating the inner spaces of the building – also recur in the Great Temple of Masjid-i Sulaiman, which otherwise shows a connection with Mesopotamian religious architecture through its possession of a forecella and cella unit behind a court (Ghirshman 1976). The identity of the deities worshipped at Masjid-i Sulaiman and Bard-e Neshandeh still remains uncertain. Nevertheless, the numerous fragments of stone sculptures (statues and reliefs) dated to the first/second century CE and depicting rulers and officials testify to the importance played by the two sanctuaries, at least in the first century of our era (Martinez-Sève 2004: 197–198).

From the village of Kal-e Chendar, in the valley of Shami, come the famous over-life-size

bronze statue of a nobleman in Parthian dress, fortuitously found in 1936. The site was briefly explored by Aurel Stein: a few days of excavation allowed him to recognize Shami as a sanctuary of Hellenistic and Parthian Elymais, whose importance is testified by the quality of the sculptures found on the spot. A joint Iranian-Italian archaeological expedition has recently resumed excavations there, bringing to light remains of structures built on monumental terraces adjacent to the one explored by Stein. In the whole area surrounding the terraces, tombs of various types have been recognized (Baqherian et al. 2016).

The materials of Parthian-era Susa testify to continuity with the Seleucid phases: epigraphic evidence – still written in Greek – attests the persistence of Greek traditions and institutions. The western influence is evident also in the figurative arts: besides the above-quoted terracotta figurines, which are generically dated to the Seleucid-Parthian period, some fragments of stone sculptures that include a well-known female head with a Greek inscription on the crenelated crown are worth mentioning. In the sculptural production from Susa, iconographies inspired by Hellenistic art coexisted with purely Iranian types, such as men in Parthian dress that closely recall – in spite of the difference in size and material – the abovementioned statue of the Parthian prince from Shami.

Hellenistic culture left a clear mark on the plan of Ecbatana, a former Median and Achaemenid capital: recent excavations have demonstrated that the regular grid of the city dates to the Parthian period. Likewise, the palace of Khurheh in the central Iranian plateau, with its slender columns with Ionic capitals, has been interpreted in the past as a Seleucid temple, but it was founded in Parthian times.

The stuccoed decoration – already seen in Mesopotamian architectural decoration – is a distinctive feature of the palace of Qal´eh-i Yazdigird, most likely the seat of a local ruler. This palace dates to the late Parthian era and is located on the westernmost slope of the Iranian plateau, not far from the Zagros gates that connect Iran and Mesopotamia. The extremely rich decorative patterns include not only abstract motifs and architectural elements but also figural motifs both of Greco-Roman and Eastern origin (Keall et al. 1980). The excavator of the palace also hypothesizes the presence of *iwan* chambers.

From Elymais comes an important series of rock reliefs that date from the first to the early third century CE, which is otherwise the time when the area was ruled by local dynasts

Seleucid, Parthian Mesopotamia, and Iran, Archaeology of, Fig. 9 Hung-e Azhdar (Khuzestan). Rock relief (Photo courtesy Centro Scavi Torino and Iranian Center for Archaeological Research)

(Fig. 9). These reliefs, often carved on boulders, usually depict reclining figures, scenes of devotion, investiture, or homage to the prince; hunting scenes and riding figures are less common (Kavami 1987: 88–130). The reliefs from Elymais are the product of a local, provincial art. Nonetheless, they share meaningful stylistic features with the above-quoted artistic production of Syria and Northern Mesopotamia in the late Parthian period; they are characterized by frontality, paratactic distribution of the figures taking part in a scene, and descriptive taste in the rendering of the details. These common traits were already highlighted in the late 1960s by Daniel Schlumberger, who explained their birth in different regions of the Parthian Empire by hypothesizing that they might have been reflections of the lost court art of Ctesiphon (Schlumberger 1970: 152–160).

Semiotics in Archaeological Theory

Alexander A. Bauer
Department of Anthropology, Queens College, CUNY, Flushing, NY, USA

Introduction

Archaeological interest in semiotics, or the study of signs, has a long history due to the centrality of interpreting "meaning" in the archaeological record. It has had particular currency with respect to questions of symbolism and style, two areas traditionally associated with the Saussurean language-based model of the sign that underlies structuralism. Its emphasis on linguistic codes and meanings also found favor among archaeologists interested in terminological classification schemes and computer applications, especially the use of artificial intelligence modeling. The limited interest in structuralism or even symbolism within Processual archaeology, on one hand, and the turn toward poststructuralist approaches within Post-processualism, on the other, however, reduced the overall impact of Saussure's structural semiotics in archaeology. In spite of this, semiotics has recently been undergoing something of a renaissance as archaeologists have turned to alternative semiotic models, in particular that of the American philosopher Charles Sanders Peirce, best known as being the founder of pragmatism. This entry presents an overview of the two main types of semiotics, that of Saussure and Peirce, and reviews their archaeological applications and key contributions and then closes with a discussion of the current and future prospects for semiotic approaches within archaeology.

Definition

Semiotics is the study of signs and the ways in which they convey meaning. The term comes from the Greek word *semeion* ("sign") and has

been the focus of philosophical debate since Plato. At the heart of such debates is the question of how well signs – and most often linguistic signs, or words – represent reality or truth in the world, and what the precise relationship is between the sign or *that which represents* and idea or thing *being represented* by the sign.

The two most influential approaches to semiotics were both developed around the turn of the twentieth century: those of French linguist Ferdinand de Saussure (1857–1913) and American philosopher Charles Sanders Peirce (1839–1914). Saussure's has had a lasting effect on anthropology and, to a lesser extent, archaeology, since its adoption as the foundation of structural analysis by Claude Lévi-Strauss. Peirce's approach, largely ignored for the half-century following his death, has more recently found favor in both anthropology and archaeology.

Saussure termed his approach *semiology* and though he acknowledged that nonlinguistic signs such as rites and customs act as signs, he focused mainly on linguistic signs as he felt those were the most complex types of signs. Understanding a language system could thus provide insight into all other dimensions of a culture. In Saussure's model, the sign is the fundamental unit of analysis and consists of two interrelated components, the "signifier" (*signifiant*), or the form of the sign itself, and the "signified" (*signifié*), or the concept being represented by the signifier (Fig. 1).

For example, the word "tree" is the signifier for the concept of that thing with branches and leaves known as a tree. Two key points about Saussure's model follows from this: (1) the concept being signified is not the instantiated thing in the world, but rather the mental concept or idea of that thing and (2) the relationship of the signifier to the signified is arbitrary and based on a social/linguistic group's convention. There is no necessary relationship between the word "tree" and the concept it represents, as other languages have other words for the same concept, such as "arbre" in French and "ağaç" in Turkish. A complete language system depends on the interrelationship among its various words/signifiers, and the aim of linguistic analysis is to understand the structure and rules at the core of that system.

Peirce's *semeiotic* model differs from Saussure's approach in several ways. First, rather than accord special status to language, Peirce conceived of all things in the world, even thoughts and humans themselves as signs. To Peirce, words are only one particular (and quite limited) kind of sign. Second, and perhaps most important, Peirce's understood signs to be triadic, rather than dyadic in nature. Rather than consisting of a signifier that stands for a signified idea, Peirce understood the sign as "something which stands to somebody for something in some respect or capacity" (Hartshorne et al. 1938–51: 2.228). In other words, Peirce understood a sign to represent its "object," or thing out there in the world, for some interpreter of that sign. The resulting interpretation in the mind of the interpreter is itself a new sign, termed the "interpretant," which stands in triadic relation with both the sign being interpreted and the object that sign was meant to represent (Fig. 2).

In this way, Peirce both acknowledged that there is a physical world "out there" which

Semiotics in Archaeological Theory, Fig. 1 Saussure's model of the sign

Semiotics in Archaeological Theory, Fig. 2 Peirce's model of the sign (after Parmentier 1994: 10)

impinges upon and constrains interpretation, while at the same time recognizing that any interpretation of the world is not direct but mediated through signs generated through the act of interpretation, interpretation itself being a sign. The implication of this is the third important difference with Saussure's model: that rather than being a closed "system," semiosis may be understood as continually unfolding in two directions, both by endlessly generating new signs in further acts of response and interpretation and by referring back to previous signs in the semiotic chain.

Historical Background

Saussure and Structuralism

Saussure's focus on codes and structures as being key to linguistic analysis was taken up in anthropology by Claude Lévi-Strauss (1963 [1958]) and formed the basis of his structuralist approach. He suggested that anthropology uses Saussure's framework to determine the binary logic of categories that constitute all aspects of social life. Through the analysis of the constitutive elements of various aspects of a society – its kinship terms, its myths, and its cuisine – Lévi-Strauss felt that the researcher could uncover the codes and "deep structures" underlying thought and behavior in a given culture.

While Lévi-Strauss had enormous influence in anthropology (though few will today claim that his results are either replicable or even reliable), structuralism's influence in archaeology was limited. While sharing some of the positivist goals of Processual archaeology, structuralism's emphasis on symbolism and meaning did not easily fit within the largely ecological framework of Processualism. Nonetheless, we can identify several ways in which Saussure's approach influenced archaeological thinking in the 1960s and 1970s.

The most direct archaeological engagement with Saussure's linguistic model and structuralism was that of American historical archaeologist James Deetz in his book *Invitation to Archaeology* (Deetz 1967). In that book, he advocates studying the elements of culture as signs and, taking up Saussure's approach explicitly, argues (1967: 87), "there may be structural units in artifacts which correspond to phonemes and morphemes in language… reflecting an essential identity between language and objects in an structural sense." He then coined the terms "factemes" and "formemes" as material correlates to Saussure's "phonemes" and "morphemes" as a way of categorizing specific artifact types in order to identify the grammatical rules underlying the relationships among them. Deetz's approach was taken up by several of his students, most notably in work by Mary Beaudry (1988) and Ann Yentsch (1991).

Structuralism and its focus on grammatical categories have also been influential in analyses of artifact style and meaning. Dorothy Washburn's (1977) symmetry analysis of polychrome pottery design, for example, builds on the idea that information is encoded within particular design elements like a linguistic code or grammar and that particular design structures displayed on painted pottery is therefore reflective of social interaction among pottery-making groups. Similarly, Hodder (1982a) drew on symmetry analysis and structuralist ideas about grammar in his study of Nuba material culture. At the same time, though, Hodder (1982b, 1986) raised important questions about the limitations of a structuralist approach and (along with his students) began a move away from it toward the discourse and text model of poststructuralist theorists such as Derrida, Ricoeur, and Foucault.

A final important application of Saussurean semiotics within archaeology is built upon the problem of grammar and terminological meaning to focus on how archaeologists themselves name and categorize artifacts and how differences in those terminologies can affect what kinds of archaeological knowledge are produced. This was the problem taken up by French prehistorian Jean-Claude Gardin (1980), whose work drew upon both Saussure's semiotics and elements of Peirce, mediated through the work of Umberto Eco (1976). Of particular concern to Gardin was the issue of how the language of archaeology could be standardized both for the sake of translation among scholars working in different languages and traditions, and for computational and

artificial intelligence (AI) applications (Gardin 1987; Gardin and Peebles 1992).

In spite of these applications, a good deal of skepticism remained about the applicability to archaeology of Saussure's linguistic model (e.g., Hymes 1970) and structuralism in general (Wylie 1982). Part of the reason may be due to the poor fit between Processual archaeology and a semiotic approach that was largely concerned with interpreting symbols. More than that, however, is the fact that, as Hodder (1989: 73) argued, material objects depart from the Saussurean linguistic model because their meanings are often nonarbitrary, they are polysemous and ambiguous, and they have durability that spoken words do not.

Current Debates

Recent Engagements with Peirce

In spite of the important critiques of earlier (mainly Saussure-based) semiotic applications in archaeology, semiotics has recently witnessed a resurgence of interest, mainly due to the (re-) discovery of the semiotic writings of Charles Sanders Peirce (Preucel 2006). Peirce's anti-foundational approach (which inspired the philosophy known as pragmatism), coupled with his view that the meanings of signs are not fixed as in a code, but are continually remediated in the process of communication and semiosis, parallels critiques raised by Post-Processualism. At the same time, the growing popularity of Peirce among linguistic anthropologists concerned with problems of discourse and contextual meaning (e.g., Silverstein 1976; Parmentier 1994), as well as a new project dedicated to editing and publishing his entire corpus (The Peirce Edition Project, based at Indiana University), has made his work newly accessible to archaeologists.

Most critically, Peirce's semiotics addresses the very problems with material culture meaning identified by Hodder (1989). In his most oft-cited contribution, Peirce argued that most relationships between signs and the objects they represent are not "arbitrary" in the Saussurean sense, but necessary, and he typologized such relations as either "iconic," "indexical," or "symbolic." This distinction (and trichotomy) was the subject of the earliest archaeological references to Peirce (e.g., Conkey 1982 [via Jakobson, Sebeok, and Eco]; Chase 1991; Byers 1994; Deacon 1997), as most archaeological interpretation is grounded in iconic and indexical meanings (e.g., the distribution of artifacts, how things mediate social relations, how style and function are related to materiality). His semiotic model also offered a way to account for the seeming ambiguity or polysemy in a sign's meaning, since he argued that any given sign may variably function as an icon, index, or symbol, depending on the particular interpretation generated (what Peirce called the "interpretant") in the mind of the interpreter of that sign.

The first substantial engagement with Peirce in archaeology was by Preucel and Bauer (2001), in which they argued that Peirce offered a way to deal with the problem of ambiguity in material culture meaning and provided a framework for not simply dealing with, but building a rigorous archaeology upon, seemingly incommensurable approaches to archaeological interpretation. Preucel followed this with a book-length treatise on the subject (Preucel 2006), and several of his students took up the challenge of applying Peirce to various questions in archaeology (Bauer 2002, 2013; Capone and Preucel 2002; Coben 2006; Cipolla 2008; Liebmann 2008). Since then, Peirce's ideas have been increasingly invoked, highlighting the broad potential of the approach in helping to answer questions of archaeological interest. While several have focused on epistemological issues (e.g., Knappett 2002; Lele 2006; Watts 2008), Peirce's model has also been applied to understanding material culture style and technology (Capone and Preucel 2002; Joyce 2007; Agbe-Davies 2010); architecture (Ferguson and Preucel 2005; Coben 2006), bodies (Crossland 2000), and religion (Aldenderfer 2011).

Peirce's ideas are particularly relevant to current discussions about materiality and the agency of material culture. As described above, Peirce argued that all signs (including material objects) actively mediate interpretation in the ongoing process of semiosis, effectively generating new signs (interpretants) as interpretive responses. This view intersects recent ideas about material agency, where objects are seen to play an active role and

even demand certain actions through their very existence. But while those approaches seek to break down the barrier between structure and agency (Dobres and Robb 2000), and human and nonhuman agents (Knappett and Malafouris 2008), Peirce's model at its core avoids the Kantian dualism underpinning Saussure's model of the sign that these theories seek to transcend. Rather than focusing on how objects do or do not represent "reality," by adding the third dimension to the sign relation, Peirce instead focused on the act of interpretation itself, to consider the ways in which such interpretations about reality were made. This "pragmatic" approach was not meant to suggest that a real world didn't exist, but that it was not directly accessible in the interpretive act. Instead, what something "means" depends on what kinds of interpretations are being privileged in each moment of semiosis. Peirce's model thus offers a way to think through material culture's active and meditative role in social life, but from the perspective of an active interpreter rather than in the object itself.

International Perspectives

Outside of Anglo-American archaeology and anthropology, almost all engagements with semiotics draw upon Saussure's ideas, particularly since his work and ideas were widely disseminated (and critiqued) through the work of a number of important twentieth-century linguists and philosophers, including Louis Hjelmslev, Valentin Voloshinov, Mikhail Bakhtin, Roman Jakobson, and Umberto Eco. Voloshinov and Bakhtin raised important critiques of Saussure's emphasis on language structure at the expense of its experiential, dialogic qualities, criticisms that parallel Peirce's ideas about mediation, though it is unlikely that they ever read Peirce. Jakobson, a founder of the influential Prague School of Linguistics early in his career, both built on and departed from Saussure's model in his analysis of sound systems. After his move to the United States later in his career, he incorporated Peirce's ideas into his thinking, in turn influencing his student at Harvard, Michael Silverstein. Otherwise and until recently, most scholars outside the United States who have engaged with Peirce's ideas have done so through Umberto Eco's (1976) work, which builds on both Saussurean and Peircean approaches.

Gardin's (1980, 1987) work on the relation of language to archaeological terminology and meaning is perhaps the most internationally well-known application of semiotics in archaeology. Gardin's focus on the problem of translation in archaeology has been a particularly important question of how to transcend academic language barriers, which he attempted to address through the use of computer applications and AI modeling. In short, Gardin argued that if some universal code for categorizing and describing artifacts were developed, scholars from different countries could share and compare data much more easily and without confusion in meaning. While some attempts have been made to employ Gardin's ideas, the issue of translation and artifact meaning remains a difficult problem in archaeology.

Future Directions

While semiotic perspectives that directly build on Saussure's writings have largely fallen out of favor in archaeology, his impact can still be felt in the numerous post-Saussurean approaches popular in contemporary social theory (particularly those of Bakhtin, Ricoeur, Foucault, and Bourdieu). Approaches that build on this work often still wrestle with the dualistic sign at the core of Saussure's system, seeking ways to transcend the objectivism assumed by its oppositional structure of meaning relations. Theories of agency and practice increasingly invoked in archaeology seek to highlight the recursive nature of structure and agency and thus see signs such as material objects as actively reinforcing, shaping, and challenging social life.

One potential impact of a Peircean semiotic approach is in laying the foundation for a pragmatic archaeology, one that is committed to understanding the various ways that individuals and cultures mediate their social lives through signs (Preucel 2006; Preucel and Mrozowski 2010). Such an approach is important for the epistemology and ethics of archaeology in the

twenty-first century. In the aftermath of the Processual/Post-Processual debates of the 1990s, the diversity of interpretive approaches has expanded to the point that some fear an irreconcilable disciplinary divide. At the same time, indigenous and other perspectives are challenging many of archaeology's core assumptions and methods and demanding an archaeology that addresses a broader range of concerns. As a non-foundational approach, pragmatism offers a way to recognize and productively build upon multiple voices, perspectives, and ways of knowing the world in the interpretive process, and suggests that such disunity adds strength to our inquiries about the world. Moreover, as Preucel and Mrozowski (2010: 33–34) argue, a pragmatic archaeology is one that continually challenges current understandings and is open to new dialogues leading to "meaningful social action."

Sensory Archaeology

José Roberto Pellini
Departamento de Antropologia e Arqueologia, Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil

Introduction: Senses as Material and Discursive Construction

We are embodied beings and thus we come into contact with the materialities of the world through our bodies and our senses. The senses represent the most fundamental domain of our engagement with the world, the means by which all values and practices are performed. Even our memories are created and activated through our sensorial relationship with the material world. Without our senses we would lose our ability to affect and be affected by the world and by other bodies, because the senses set in motion assemblages of bodies through lights, sounds, colors, textures, moods, temperatures, odors, emotions, tastes, and narratives, and without the senses the affective flows that move these set, which Deleuze (1984) calls the assemblage, would cease to exist (Pellini 2018).

In the same time, we need to consider that the perceptual reality, that is, what a body perceives, is not something external to the body, a fixed and preexisting reality, but it is something that emerges from our material and discursive engagement in each different situation of daily life. The reality of what is perceptible is not in the promulgation of perception but in its actualization. As Hammarstrom (2015, p. 176) would say, "a measure does not measure something non-existent in existence but actualizes one of the possibilities of the perceptible."

The sensorial perception is a process involving human and nonhuman, matter and discourse, subjects and objects in a relationship of mutual constitution. We cannot say that the senses only pertain to humans and that only humans could feel and perceive. Existence is not an individual affair (Barad 2007, p. ix). Sensing, is not an individual nor exclusively human affair, but it is a

process enacted by a material-discursive practices, where to make sense through the senses is to consider the distribution of the senses among all the elements of a relationship. Hayward (2017) proposes to think that sensations are relational processes distributed among the entities present in a relation, that is, sensations are formed by the convergence force of perceiving, feeling, affecting, and being affected. The author named this process of *ciliated sensuousness.* The senses cannot be reduced to a mechanical or biological phenomenon or even to a social construction. The senses are neither subject nor object, but a relational ontology that brings meanings, memories, bodies, materialities, and discourses together during a relationship. Likewise, the human and nonhuman, subject and object, sense and making sense are not independent entities separated by clear cut boundaries but entangled phenomena whose ongoing intra-actions produce an endless series of local and contingent configurations of reality (Mcnay 2016).

As a material and discursive practice, the senses cannot be thought without the affects, the memories, the corporal practices, the education, discourses, and narratives. Different relationships imply different reconfigurations of this set. As Labanyi (2010) shows us, the materiality of experience is ever changing, since the human sensorium is always updating itself and what is experienced as experience is always variable.

Definition: An Archaeology with Senses

Despite our senses' importance in our lives, archaeology has generally given little attention to them. This is, first, because the senses are recognized only as physiological tools and not as material-discursive practices subject to cultural influences. Secondly, even among those who recognize the importance of culture in the senses, many believe that they are too ephemeral to be analyzed scientifically. However, this is not the case, for, since sensory experience is material, it requires materiality in order to be activated and thus to work with the materialities is to work with the senses. Thirdly, archaeology remains a scientific discipline that privileges vision as an instrument of analysis. Much of archaeology takes the form of a testimony of appropriation where testimony implies more than looking. It means establishing a psychological relationship where the observer is superior to the object of observation. The directionality of observation is from us to them. Fourthly, archaeology, born within the Western colonial and modernist project, communes and perpetuates a distant form of relating to the materialities of the world. As a result, we end up excluding other possibilities and ways of apprehending the world other than those based on the Western Aristotelian model. Worse, by focusing only on vision as the only legitimate way of relating to the world, we are assuming that those we want to analyze share the same sensory model as ours, and we are thus categorically discounting the possibility that the other's world may be different. *This practice limits our understanding of the past.* Take, for example, the case of the Desana of Colombia, who differentiate their baskets according to the odor of the straw they are made of. According to Reichel-Dolmatoff (1985), among the Desana, besides their utilitarian character, baskets have a symbolic value that is directly associated with the odor and texture of the raw materials used for their preparation, since the odors and textures of the different fibers used in these objects' creation make direct reference to Desana mythology. In a traditional, vision-centered archaeological approach, the classification of Desana baskets is likely to be based on visual indices such as shape, decoration and style. Such a system would have no meaning among the Desana, simply because they, unlike us, do not order their world through visual forms but based on odorous manifestations. In this way, what is the point of ordering all Desana baskets according to sizes, shapes, colors, and designs if what matters to them is the raw material's smell?

In this context, the proposal of Archaeology of Senses is not to demonize vision, much less to elevate the position of minor senses into dominant ones, but to investigate the way in which meanings are invested and conceived through the senses. Archaeology of Senses seeks to

understand how people produce their subjectivity, their collective identity, their experiences, their daily routines, and how they built their own history through the sensory and affective experience of matter, animate and inanimate beings, humans, and plants (Hamilakis 2012).

Current Debates: Archaeology and the Senses

In general, the Archaeology of the Senses usually focuses only on the five Aristotelian senses, and the vision is the most explored sense both in practice and archaeological interpretation. The visual aspects have been explored, for example, in the significance of colors and visibility profiles. For Whitley et al. (1999), the sensorial qualities of raw materials must be considered together with their technological characteristics. In one of their examples, the authors discuss how the quartz glow was an important tangible aspect in the choice of raw material for some societies. Jones and MacGregor (2002) have suggested that the use of rocks of different lithologies and coloring in the construction of the passageways of Mesolithic Irish tombs created a colored structure that interfered in the direction and conduction of the natural light inside the monuments; the authors conclude that the interrelationship between light, color, and specific lithologies could suggest performances associated with cosmological significance.

Pursell (2013), on the Shiloh Mounds, has shown how the use of sediments of different shades, mainly white and red, in certain areas of the mounds during the construction process acts to modify what he calls the theatrical experience of space. According to the author, many southeastern Native Americans characteristically split their ideological and their social realities into the dichotomous categories of red and white, which may be thought of as symbols of a suite of related concepts including clan and animal symbolism, tied to various personal or social attributes.

Working with the polished axe exchange system in the Neolithic period in Ireland, Cooney (2002) concluded that the polishing of axes had a function of highlighting the color of the axes, since rocks of different stains indicated specific production sites. In this sense, the coloring of the axes functioned as an index of social identity.

From the analysis of artifacts discovered at the medieval site of Sutton Hoo in England, Williams (2011) has worked with the idea of mnemonic art agency. An interesting aspect of the artifacts identified during the excavations is that most objects are decorated with eyes or take the form of eyes. The author believes that this is a clear reference to the Norse myths, especially Odin and the idea of clairvoyance.

Working with rupestrian sites in Ontario, Canada, and art sites in New Zealand, Allen et al. (2013) suggest that the tremulous reflection of water under certain walls is an effect that may have attracted prehistoric groups to use these rocks to express their iconography. Although the authors acknowledge that further investigation is needed, they suggest that there appears to be a correlation in both Ontario and New Zealand between the shimmering and the presence of paintings in nearby waterways.

Villegas and Martinón-Torres (2012), working with the votive objects of the Muisca, demonstrated how the choice of offerings was directly linked to the sensory aspects of artifact fabrication. While the majority of pre-Columbian groups generally emphasize objects made of metal, the brilliance of artifacts, color, and other sensory aspects, the Muisca value the constitution of objects – their essence, not their appearance. While we Westerners, before displaying an object in a museum, clean it, polish it, and make it shine, among the Muisca the objects are left dirty and unpolished. What is most important to the Muisca is what the object contains, that is, the alloys and the wax coming from the manufacturing process, and not necessarily what it looks like.

In relation to hearing, a number of archaeologists have explored the idea of soundscapes. In an attempt to explore new meanings for the landscape, Scarre and Lawson (2006) worked with the recreation of the ceremonial sounds of the Bronze Age. Similarly, Loose (2008) explored the sounds of screams and bells in ancient rituals.

According to King and Santiago (2011), in ancient Mexico the sensorial involvements in the form of oratory, music, and performance were the main components of the festivals sponsored by the state and the elite. Working with the Rio Viejo sites in the city of Oxaca, the authors argue that sound production created a sound landscape that was shared by all members of the community.

Boivin et al. (2007) have also explored the idea of soundscape. In studying the Sanganakallu-Kupgal region, they identified a series of sonic-capable lithologies that functioned as a kind of gong echoing throughout the region. The "gong" rocks generally support each other, being free of the ground and able to reverberate. Hitting in different places with different rocks produces a wide variety of tones. The authors suggest the idea that the valley, where the studied sites are located, formed a kind of auditorium that amplified the sound in specific points of the landscape.

The Litho-acoustic Project of the University of Cambridge is another good example of how sounds and hearing can work in archaeology. By conducting experimental studies, it has been hypothesized that hunters and gatherers could have used tools and even the process of carving stone to produce sound (Cross et al. 2002).

Odor has been one of the least studied sensory aspects in archaeology. In *L'intelligence d'un Sens: Odeurs Miraculeuses et Odorat dans l'Occident du haut Moyen Âge* (2009), Roch explores the use and meanings of odors in medieval Christianity, suggesting that odors played a central role in the relationship between the mundane and the spiritual worlds. According to the author, finding an odor was evidence of the material presence of something. The odors in medieval Christianity carried a social meaning that determined the concepts of divinity, holiness, God, the individual, etc.

According to Brazinsky and Fryxell (2013), Christian relics of the medieval period share several material characteristics that may have contributed to their unique scents. Bottles and ampoules were produced near various holy sites to serve as portable vessels for sanctification. Many of these relics were used not only to contain the sacred liquids but also as personal ornaments. In addition, ointment containers were used to produce a specific sweet smell in the tombs of saints which created a direct association between odors and holiness due to the use of incense and candles.

With regards to taste, there is an understanding that the study of it, far from being a peripheral aspect of our understanding of culture, can indeed provide a new way of studying social life. Sutton (2011) proposes a gustative analysis where taste is placed in a context in which it refers to the lives of the people, mainly with regard to the formation of identities.

In relation to touch, we must first remember that it cannot be reduced to just the touch of the hands, for touch is a complex sensation that involves the whole body. According to Tringham (1991), when we think about the tactile experience of the past in terms of movement and contact, we have to think of materials that may have made contact with the body, including tool surfaces and surfaces that act as intermediaries between the skin and the outside world or material, such as clothing, handbags, sheaths, and handles. The other important aspect in dealing with touch, according to the author, comprises the kinetics of contact, which includes pressure, variable force, direction, velocity, and friction between two inanimate materials and between the inanimate material and the human actor.

Cummings (2002), also working with touch, discussed how some European stone circles and megaliths were constructed on the basis of tactile aspects. In Bargrennan in southwestern Scotland, for example, a stone chamber has different lithologies on the walls of its inner part to guide the movement of people, given the restriction of light inside the monument.

The South American Way

Although South American archaeology remains closed and mostly culture-historical, works that attempt to discuss the senses from the bias of material culture have grown exponentially. One of the pioneers of this field, at a moment when there was no mention of an archaeology of the senses, was Tania Andrade Lima. She worked

with the odors of the city of Rio de Janeiro in the nineteenth century in the identification of laxative substances and clysters (Lima 1996). For the author, the abundant presence of these materials in domestic dumps suggested a scenario where the body and the senses were being disciplined.

Melisa Salerno is another scholar who has dedicated herself to the work of sensory archaeology for a long time. Recently, the author, with Andrés Zarankin and myself, edited two books on the subject. The first, published in 2015, is called *Coming to Senses: Topics in Sensory Archaeology*. The book is the result of papers presented at the Symposium on Sensory Archaeology, which we coordinated at the 2013 World Archaeological Congress in Jordan. The second book, *Undisciplined Senses*, is the result of the discussions on archaeology and the senses during the Theoretical Archaeology Congress of South America (TAAS) that took place in Chile in 2014. Apart from the two books, the author has a long tradition in the themes involving the senses and the body in general. The author discussed the contexts of repressive regimes in Argentina and those associated with the occupation of Antarctica (Salerno 2011, 2015). In the latest, in analyzing the shoes identified during the archaeological excavations in the South Shetland Islands, she identified two different types of footwear: one long boot type and the other short. The long shoes had leather soles and showed a better quality of materials and finishing, which indicates that they were more expensive. By contrast, the short footwear had wooden soles covered with leather and a lower quality finish, resulting in footwear of lower cost and more connected to the working classes. According to the author, by hindering the movement of the ankle, boot-like footwear results in wider steps with the legs well stretched. For Salerno, such a way of walking is associated with the supposed elegance and pride of those in power. In the case of the short shoes, the author shows that the leather covering of the wooden sole is a clear indication of the lower quality of these shoes, since they tried to imitate the shoes with leather soles. In these low-cost shoes, the wooden sole prevented the correct flexibility of the feet, and this resulted in an awkward, unsafe, and unsightly type of walk.

Jimena Cruz, also working on the Antarctic seal hunter groups during the eighteenth and nineteenth centuries in her 2014 master's dissertation in the graduate program in Anthropology at the Federal University of Minas Gerais, discussed how foods can be thought of as elements of identification of different social behaviors. She shows us that there was a great difference between the food made on the boats during the voyages and the meals provided at the ground hunting camps. In the boat, the food consisted mainly of canned goods acquired in the ports through which the ship passed. Once on land in the hunting camps, the food was mostly made with local items. At the same time, the author shows us that the differences were not only related to the type of food but also to social behavior, since while there was a certain hierarchy on the ship, with the highest posts receiving better quality food, in the ground camps there was greater equality among the people.

Marschoff (2007) also focuses his research on food, but with a different bias. His work discusses both food and cooking as mnemonic elements in order to show how individual collective subjectivities come into play in social practices. He discusses how memory is tied to both taste and cooking, since anyone who teaches a recipe has to invade the memories of others. At the same time, the author shows us how taste is used as an element of remembrance.

Kolar (2013) studied the monuments of the ceremonial center of Chavin de Huantar in Peru in order to establish, through the experimentation of musical instruments recreated from archaeological and ethnographic contexts, a relation between space and the transmission of acoustic properties, as in the case of *pututus* trumpets made of shell. The first results point to a strong acoustic correlation between the central square of Chavin de Huantar and a monolith located inside the temple of the ceremonial center.

The work of Andrés Troncoso is another good example of the application of sensory archaeology in South America. Working with rock art from

northern Chile, he compares the paintings of hunter-gatherers with the petroglyphs of agricultural communities. According to Troncoso and Armstrong (2017), the production and consumption of rock art is historically contingent and thus the differences between these two types of art are not only a difference of technique but a difference linked to the ways of conceiving and experiencing art in the body. According to the author, paintings associated with hunter-gatherer groups are usually found in living areas, which means that the experience of art is daily and communal. At the same time, he points out that the use of pigments derived from various local minerals shows a deep knowledge of the landscape. This creates a bond between the painting and the landscape that integrates the art with its surroundings. Pigments in Troncoso's work can be seen as agents in their own right. They can be thought of as acting as the animation of rocks and supports. Art in this sense acts as an animated medium through the use of pigments. Troncoso considers the act of painting under the rock a bodily act, which involves not only sight but also and above all touch.

Alexandre Herrera (2007), working with *pututus* and *kepas* (aerophones made of shell), has discussed the creation of sound landscapes in the Andean highlands and their importance in the constitution of a sense of place. Usually associated with public festivals and rituals, the aerophones, with their loud sound sometimes reminiscent of thunder, created an ambience that generated intense mnemonic processes.

Andrés Zarankin is another author with a long tradition in working with the body and the senses. His work on the structures of visual control of regimes of repression in Argentina with his *Walls that Domesticate* (2002) discusses the use of the panopticon by the dictatorship as a form of control of so-called subversives.

In this South American scenario, an important initiative for the development of sensory studies within archaeology was the creation of the Laboratory of Sensory Archaeology at the Federal University of Minas Gerais in Brazil. Created in 2013, the LAS already has seven researchers and a number of undergraduate and graduate students in archaeology. Among the topics are rock art, with the discussion of the sensorial aspects associated with the apprehension and production of their iconography; sensory aspects associated with the implantation of prehistoric and historical sites within the landscape; analysis of the sensory properties of objects; social discrimination; religion; artifacts and musical landscapes; memory; and color.

The Future: An Archaeology of Senses and Affects?

By working with the senses, we approach the possibility of breaking with the political and ideological continuum that has colonized us and forced us to perpetuate specific sense-racial hierarchies, discourses of power and worldviews (Ouzman 2005). For Hamilakis (2012), perhaps the main potential of Sensory Archaeology is its ability to reshape the field of Archaeology, freeing the discipline and archaeologists themselves from their modernist and ocular-centric currents by adopting a multisensory and mnemonic practice. We need to un-discipline our senses, rethink our scientific practice and our role as producers of truths. It is no longer enough to recognize that the hegemonic scientific discourse colonizes, violates, and shapes our lives. It is not enough to understand that we cannot treat other people's worldviews as something smaller and exotic, a deviation from Western and scientific ontologies. It is not enough to recognize that we need to think of a different archaeology, an archaeology that is in essence relational and post-human. We need to stop talking and start changing. But how to act if most of the time we do not provide an account of how we reproduce hegemonic discourses?

In this way, our first step would be to decolonize the senses, because this is the only way we can break up with the modernist hegemonic structures that determine the senses as purely human, formal, and apolitical elements. According to Mignolo (2013), only the decolonization of normative sensorial models can allow us to awaken from the situations of shock and anesthesia to which we are submitted in our everyday lives. For Mignolo, to decolonize our senses is a

movement toward a democratic future that goes beyond the concept of democracy in the West. We must recover our critical capacities and understand that our senses are educated within an aesthetics that violates, segregates, and discriminates. We need to understand that our perception has been naturalized and that the sensing and making senses is not a human capacity. We do not question why we only trust vision as a source of truth. We do not question why we do not touch objects or people. We do not question why we like certain scents and dislike others. Everything appears very natural. The problem is that it also seems natural for us to think that if the body smells good, then it is naturally clean.

We need to free our senses because this ultimately means decolonizing the modernist, postmodernist, and multiculturalist logics governing archaeology today. Decolonized aesthetics is a tool to confront a world crowded with the situations of shock, anesthesia, merchandising, and information that invade our lives and confine our creative and imaginative potential. In this way, to think of an archaeology with senses is not only to use the senses as a tool of analysis for past and present societies or to see how societies conceive their world, identity, histories, and memories through the sensorial experience of matter, but to consider the sensorial, affective, and emotional relations that we have with the world around us. We need to change not just as scientists – we need to change as human beings.

Sepphoris, Archaeology of

Aaron M. Gale
Program for Religious Studies, West Virginia University, Morgantown, WV, USA

Introduction

Sepphoris was a major ancient city located in lower Galilee, in what is today Israel. Most prominent in the Roman era, the city was located about 6 km from Nazareth. Sepphoris became an important commercial and political center in the first century CE, and likely due to this affluent economic status, its residents did not actively take part in the Jewish rebellion that took place from 66 to 70 CE. Ultimately, Sepphoris fell into decline during the Islamic era. In the twentieth century, largely due to its proximity to Nazareth, the childhood home of Jesus, the site attracted the attention of biblical scholars and archaeologists, and many excavations have taken place over the last several decades. Although never actually mentioned in the Bible, scholars have long sought to uncover any possible links that may exist between this ancient city and Jesus. In addition, ancient historians have maintained an interest in Sepphoris because of its prominent status in the Roman world.

Definition

Known in Hebrew as *Tzippori* (from the word "bird"), Sepphoris was a major Roman city located in lower Galilee that thrived from approximately the first century BCE through the seventh century CE. The name *Tzippori* is a reference to the city's prominent location perched upon the top of a hill (286 m above sea level) in the Beit Netofa Valley (Batey 2001). The city's location was also strategic due to the fact that it sat at the intersection of two major roads. Little is known of the city's early history prior to its rise to prominence in the first century BCE, although it is likely that the city existed much earlier. Archaeological

evidence has been found dating as far back as the Iron Age. This evidence, mainly in the form of pottery fragments, is sparse. Scattered pottery sherds as well as vase fragments and a rhyton date from the Persian era (Chancey 2001). However, no firm architectural evidence has survived from this time period. Therefore, the city was likely functional, yet still small, during the Persian era. During the Hasmonean era, around 104 BCE, the historian Josephus notes that the city was attacked by an invading Cyprian king, Ptolemy Lathyrus (*Ant*. 13.338). This, in fact, is the first historical reference to Sepphoris by Josephus, and from this point on, the city is mentioned frequently in his histories. This suggests that Sepphoris was probably an established city by the first century BCE. However, it is only with Rome's ascension to power that Sepphoris rose to its greatest heights.

Several years after the Roman takeover of Palestine at the hands of Pompey, around 55 BCE, Sepphoris was elevated to the status of council seat (for the Sanhedrin) after a visit by the proconsul in Syria, Gabinius (*Ant*. 14.91). By this time, the city was probably largely Jewish and would remain so for the duration of its existence. There is no evidence to suggest a strong Roman presence within the government and everyday affairs of Sepphoris (Chancey 2001). Herod the Great retained the city during his reign (beginning in 37 BCE) until his death in 4 BCE. Upon his death, Jewish nationalists in Sepphoris revolted against the Romans, resulting in a legion being sent in to subdue the city (*Ant*. 17.271). Much of the city was destroyed as a result of the riots. Out of the ashes came a renewal effort instigated by Herod's son, Antipas. Hence, Sepphoris became a fortified, cosmopolitan Herodian city, and Antipas made it his capital until Tiberias replaced it some 20 years later. The city was rebuilt in a typical Roman grid fashion, with a main east–west street (*decumanus*) intersecting with a main north–south one (*cardo*).

During this period of growth and fortification, Josephus refers to Sepphoris as the "ornament of Galilee" (*Ant*. 18.27). It has been suggested that this phrase was only used when referencing strongly fortified and secure cities (Miller 1984). In the latter twentieth century, many facets of the ancient Roman city were uncovered, including a paved road system, a first-century villa, an aqueduct, cisterns, two marketplaces, a cemetery, and a theater. Population estimates for first-century Sepphoris range anywhere from about 10,000 to 25,000. Surveys conducted in the early twenty-first century suggest that several small "satellite" settlements may have sprung up near Sepphoris during the Roman and Byzantine eras, which indicate that the city's robust economy spurred the creation of small support villages nearby (Dark 2008).

During the Jewish revolt of 66–70 CE, most residents of Sepphoris, although mostly Jews themselves, chose a pacifist stance and did not fight against the Romans (*War* 2.574). Archaeologically, the most significant finds from this period are probably the pro-pacifist Roman coins, which date from the year 68 CE. The coins, minted in Sepphoris, were meant to honor the emperors Nero and Vespasian. Most noteworthy, however, was the inclusion of the Greek inscription "City of Peace" (Reed 2000). Also relevant is the fact that none of these coins exhibit a portrait of the emperor, suggesting a willingness to adhere to Jewish tradition, which forbids human images on coins.

Following the revolt, and despite Rome's victory, Sepphoris became a vital center of Jewish learning, as rabbinic texts indicate. The most famous Jewish tradition linked to Sepphoris was the belief that the Mishnah was recorded in the city by Judah Ha-Nasi early in the third century CE. Archaeological remains from the late Roman and early Byzantine periods are plentiful and point to a time of renewed building. This is especially the case in the late first and early second centuries. Revamped water systems, additional roads, an agora, and a Roman bathhouse have all been found, and the city became known in the Roman world as Diocaesarea. Some estimates have placed the size of Sepphoris in the late Roman era at about 35 ha (approximately 86.5 acres).

Yet the population of the city remained mostly Jewish, although Hellenistic and Roman influences may have become more prevalent at this

time, as coins now bearing busts of the emperors indicate (Chancey 2001). In addition, Greek inscriptions have been found at Sepphoris dating from the late Roman and early Byzantine periods, further suggesting the presence of pagan inhabitants. Noteworthy archaeological finds from the Roman period include the discovery of a third-century basilica-like building (70 × 95 m) and a private residence (48 × 23 m) containing exquisite mosaics. The former structure, however, remains somewhat of a mystery regarding its function. The two most popular theories are that it was either part of a marketplace or it was an actual basilica. The latter structure has become known as the house of Dionysus, since many of the mosaics pertain to the life and cult of this Greek god of wine and fertility. Most noteworthy, the house of Dionysus contains a mosaic housing what has become known as the "Mona Lisa of the Galilee." This mosaic, found on the floor of the residence, contains the face of a beautiful, unknown woman. The discovery of the "Mona Lisa" has been called one of the "Ten Most Significant Finds" of the twentieth century by Biblical Archaeology Magazine, although some experts downplay the importance of this assertion (Fig. 1).

Sepphoris itself continued to thrive into the Byzantine era, despite earthquakes and periodic revolts. Remains of a fifth- to seventh-century synagogue have been found, containing a floor mosaic complete with a picture of the Zodiac. By this time, it was not unusual to find traces of Hellenistic influence in Jewish buildings, even synagogues. In addition, the remains of two churches have been uncovered on either side of the *cardo*. Christianity likely gained a foothold in Sepphoris by the fifth century (Miller 1984). In recent years, a second-century pagan temple has been found, suggesting that Jews, Christians, and pagans eventually inhabited the city together until the Muslim era. The most noteworthy structure found dating from the Byzantine era may be the Nile Festival building, located east of the *cardo*. The mosaic found inside the building, known as the Nile Mosaic, is one of the most famous features of the archaeological site (Fig. 2).

After the seventh century, Sepphoris declined as a city, due to many factors, including natural disasters and wars (Ward 2001). The city became known after its Arabian conquest as *Saffuriyya*. During the Crusader era, when Christians briefly inhabited the city, a watchtower was erected on the hill, which is still visible today. Ultimately, the city was under Muslim rule until the modern era. Worth noting is the fact that although in a state of decline, Sepphoris may be the only site in Galilee that was occupied from the Hasmonean era to 1948 (J. Strange *pers. comm.*, February 2012) (Fig. 3).

Key Issues/Current Debates

The earliest major archaeological excavation of Sepphoris was undertaken in 1931 by Leroy Waterman from the University of Michigan, who was looking for a link between the city and Jesus. Virtually no additional excavations were undertaken until 1983, when James Strange (University of Southern Florida) renewed the efforts. In 1985, a joint team from Duke University and the Hebrew University of Jerusalem under the direction of Eric Meyers and Ehud Netzer, respectively, began excavating the site. Since the 1980s, work at Sepphoris has continued. In the twenty-first century, a team from the Institute for Archaeology at the Hebrew University of Jerusalem under Zeev Weiss continues to dig and provide field reports from the site. Other universities also still excavate at

Sepphoris. Some tombs from rabbis have recently been found, mostly northwest of the center of the site (J. Strange *pers. comm*., February 2012).

Although never mentioned in either the Old or New Testaments, Sepphoris remains a relevant site for biblical scholars, historians, and archaeologists. Due to its proximity to the city of Nazareth, where Jesus lived for a time (6 km), Sepphoris has been studied with an eye toward the Bible. Most noteworthy, biblical scholars have debated the cultural and religious composition of the city. In particular, the conflict centered upon whether Sepphoris contained a Jewish, pagan, or mixed population in the early Roman era. Initially, claims were made that Sepphoris was a largely Hellenistic city that attracted the attention of Greek philosophers (Downing 1987). Others argued that the city was almost entirely Jewish. However, it is possible that Greco-Roman culture was not in itself incompatible with Jewish life and practice (Reed 2000). In other words, some aspects of pagan culture (i.e., artwork, decorations) could coexist side by side within a population that still adhered to the Jewish faith. Jews would have considered them to be ornamental only and not a threat to the faith itself. Yet the debate concerning the religious nature of Sepphoris continued throughout the late twentieth century (Fig. 2).

At the dawn of the twenty-first century, the controversy seemed to peak over the issue of whether stepped pools (discovered on the western summit) were bathing pools or Jewish ritual baths (Heb. *mikva'ot*). A general scholarly consensus affirmed that they were indeed ritual baths (Meyers 2000; Chancey 2001). Additional archaeological evidence found at Sepphoris, including a lack of pig bones and the discovery of limestone vessels, has resulted in a predominating view that the city was primarily Jewish during the Roman era. James Strange believes that Sepphoris was almost 100% Jewish, at least until the second century CE (J. Strange *pers. comm*., February 2012).

One other archaeological feature is still being debated by scholars. A 4,500 seat theater was uncovered on the northern slope of the acropolis, and a controversy has emerged over the date of its construction. It has been suggested that those attempting to link Sepphoris to the historical Jesus are biased toward an early first century date. However, other scholars refute this claim, dating the theater instead to the late first or the early second century (Charlesworth 2003). Such debates have served to keep Sepphoris at the forefront of archaeological dialogue today, and the city continues to remain a relevant site for historians and biblical scholars.

Sequence and Date in Field Archaeology

Martin Carver
Department of Archaeology, University of York, Kings Manor, York, UK

Introduction

For the field researcher, a primary task is assigning a date and a sequence (order of

Sequence and Date in Field Archaeology, Fig. 1 The business of chronology (Carver 2009: 267)

occurrence) to the features and structures they record. Occasionally an archaeological site has already been recorded in history, for example, the celebrated urban excavation at Five Points, New York City, exposed a plan of buildings and streets that had appeared on a map in 1855. Even sites mentioned in documentary references seldom offer a date as precise as this, and dated events which might *seem* to refer to an excavated site have to be used with great caution.

In general, very few objects, activities, or structures discovered by fieldwork can be given a precise calendar date, and archaeologists are obliged to build a *chronological model*, which balances all the available information (Fig. 1).

Key Issues

Dating Objects

As applied to objects, the methods at our disposal are *typology*, which offers a *relative dating* for artifacts (e.g., pottery) and structures (e.g., architecture). Typology uses the likely order of manufacture, based on form and style, combined with the dates given elsewhere. For example, pottery, one of the most useful of artifacts since it occurs widely and endures well in the ground, has an enormous range of types. Some periods of manufacture are known from kiln sites, but most are deduced from which types occur together; in this way archaeologists have built up extensive typologies that help to date every kind of site built by pottery users.

Artifacts may also be given an *absolute dating*, by scientifically measuring the *age of materials* they are made from. Well-known examples here include *radiocarbon dating*, which measures the age since the death of a living plant (i.e., wood) or creature (e.g., bone); *dendrochronology*, which measure the age of timber since it was felled, from the numbers and spacing of annual growth rings; *archaeomagnetism*, which measures the age of a hearth since it was heated; and *optically stimulated luminescence* (OSL) which measures the time that has elapsed since a layer of sand was last exposed to sunlight (Hedges 2001). These dates, which have an error range from 1 year (dendro) to 25% or more, indicate when an organism died or a mineral was buried.

Dating Contexts

Absolute and relative dates for artifacts, or groups of artifacts, can be used to date the archaeological layers they are found in – but the relationship is not a simple one. A layer is always deposited later than the latest object found in it, for example, a floor with a coin of 400 CE beneath it must have been laid in 400 CE or later (since the coin must have existed before the floor was laid). This relationship is called a terminus post quem (TPQ). A wall which has a date written on it (say 1929) must have been constructed before 1929. This relationship is called a terminus ante quem (TAQ). However, these equations are by no means always valid or helpful. A coin may be not just earlier, but centuries earlier, than the floor that covers it. A coin within a floor may be *intrusive* and so later than the floor. A coin found on top of a floor may be later than the floor, if dropped on it soon after manufacture and never moved, or much earlier than the floor if carried around for decades in someone's pocket. Similarly a coin or a potsherd found in a foundation trench is usually earlier than the wall in the same trench, but it may also be much earlier since it has been displaced – is residual – from an earlier phase or site. Since we rarely know the circumstances in which a coin was discarded, it is risky to use coins to date structures. They are at least very rarely contemporary. In spite of this, equating the date of a building with the date of the coins found in it remains a widespread practice.

Structures, features, and contexts may also be dated directly – by typology and by scientific dating. Typology may be applied to the shape of hearths or kilns, or the ground plans of houses, comparing them to others found elsewhere and so presuming that they can be assigned to the same culture and date. Absolute dating can sometimes be applied, for example, *dendrochronology* will date the timbers of a timber-framed house (Kuniholm 2001). However, it is frequently found that such a house, in the form it survives, is composed of structural timbers of different dates. Even the earliest of these may have been recycled from another usage – for example, in a ship. *Radiocarbon* dating is applied to carboniferous materials, such as charcoal or bone, but here the association with the deposit is of crucial importance (Taylor 2001). The charcoal in a hearth may represent the date of last burning but only if it derives from twigs or animals. Otherwise the wood may have already have been cut down long before it was burnt (the 'old wood' effect). Similarly the bones in a grave should date the digging of the grave very well, but animal bone

Sequence and Date in Field Archaeology, Fig. 2 A vertical section through consecutive layers at the early monastic site at Portmahomack, Scotland (M. Carver)

may have been disturbed and redeposited and so give a date before, perhaps long before the deposition of the layer in which it was found.

An important method applied by excavators to contexts, features, and structures is stratigraphic ordering. This does not date them but provides a *relative order* for each deposit in the overall sequence. The traditional method of presenting the order of occurrence is the section, which shows the deposition of layers from the side, and is recorded by drawing (Fig. 2), and these may still be valuable even if they only report the sequence in a specific slice through the strata. A more comprehensive method of stratigraphic ordering that applies to the whole site is the stratification diagram – which models the sequence in two dimensions, the earliest contexts at the bottom and the latest at the top (Fig. 3). These have

Sequence and Date in Field Archaeology, Fig. 3 Extract from a stratification diagram, showing the sequence of contexts and features at an urban excavation in the Stafford Town, England (Carver 1980: Fig. 51). The features are shown as vertical arrows, locating them in time. Contexts not belonging to features are shown as horizontal lines. This diagram was devised to show the sequence in a deep but poorly stratified deposit

S

developed from pioneer examples in the 1970s (e.g., Harris 1989) to more comprehensive models which include features and structures and represent uncertainties in the sequence (Carver 2009: 296). These uncertainties form an important aspect of the modelling process and show where other interpretations are possible.

The stratigraphic ordering of graves containing bone or hearths containing charcoal can be dated with much greater precision by using radiocarbon dating combined with *Bayesian analysis*. The radiocarbon dates give a range of error, but this range is reduced by knowing the order in which deposition occurred. The Bayesian analysis produces shorter ranges of probability for each date (posterior density estimates, Fig. 4). This is giving archaeological sequences of high precision dating back to 20,000 years ago (Buck 2001).

Relative Ordering by Space

The business of establishing a sequence makes also use of *spatial analyses*. For example, a settlement that is spatially coherent (like the grid of a *planned* town) suggests that all the streets and houses were laid out at the same time. Features that are *aligned* are also thought to reflect contemporary use. For example, inhumation graves in a cemetery may have different orientations, but those that are most closely aligned are said to be close to each other in date. Similarly, graves that mimic the orientation of a building are later in date than the building. On the scale of a landscape, alignments are important indicators of sequence. Roads and field boundaries seen from above may indicate a sequence where they "respect" one other. For example, the field boundaries may join up to a preexisting road, or the road may cut straight across the line of the fields, showing it was imposed on a preexisting agricultural landscape.

Modelling

At the scale of a landscape, archaeologists use such spatial mapping as an indication of sequence. It is often possible to apply typology, for example, to infer the likely culture and date of cropmark forms encountered in *aerial investigation*. Similarly, forms recorded in *subsurface survey* are sometimes recognized by virtue of their shape alone: a straight

Sequence and Date in Field Archaeology, Fig. 4 A sequence of graves from the Anglo-Saxon cemetery at Wasperton, England, placed in their best order by Bayesian analysis. The outline shows the error range of the calibrated date; the solid black profile is the more precise "posterior density estimates" derived from Bayesian modelling (Carver et al. 2009: Fig. 4.1)

road or a circular ditch or a settlement grid. When using *surface survey* to find sites, archaeologists rely on typologies to provide a broad date for the pottery or stone implements or metal artifacts they are mapping. The distribution of this material provides the location of sites belonging to a particular culture and period.

On excavated sites, stratigraphic ordering provides the surest indication of relative sequence. The alignment of features and structures often give an inference of where these might be contemporary. The broad dates of objects and structures (and the very occasional documentary reference) allow a sequence to be anchored more closely in time. In well-stratified sites, such as towns, the stratigraphic sequence is treated as primary. Poorly stratified sites (the majority) rely more on relative and scientific dating of objects and samples. The method is to examine and record the detailed possible relationships of objects and strata in every case and then to use typology, stratification, spatial analysis, and absolute dating to build up a robust chronological model.

Serra da Capivara National Park

Anne-Marie Pessis
Universidade Federal de Pernambuco, Recife, Brazil

Introduction

The Serra da Capivara National Park, which covers 320,000 acres, is located in Northeast Brazil, in Piauí state. The park has a geological border where a large row of vertical walls separates two distinct formations: the plateaus that form a mountain range, and the sedimentary basin of Piauí-Maranhão (Fig. 1).

Its current climate is semi-arid. There is a brief rainy season when large amounts of precipitation produce lush vegetation, and the power of water flowing across the area causes the land to degrade. The rain period is then followed by a dry season, and the local vegetation loses its foilage. However, the climate in the region has not always been as such. Until 9000 years ago or so, when the onset of Holocene climate triggered the current desertification process the region was covered by tropical rainforest.

Definition

The Serra da Capivara National Park houses a dense and diverse collection of prehistoric

Serra da Capivara National Park, Fig. 1 Chapadas, valleys, dendrites, and *cuesta* abysses of the National Park

paintings and petroglyphs produced over the millennia. There are rock art sites are located in different ecosystems within the park, in valleys, and canyons. The rock art is more numerous inside the caves where rockshelters are at different heights from the bottom of the valley to the top of the *chapada*. Opposite to the *cuesta* is a chain of limestone outcrop caves. There appear to be no traces of paintings or engravings inside them other than an occasional isolated motif at their entrances.

Key Issues/Current Debates

Since the 1970s, more than a thousand sites with prehistoric paintings and engravings have been identified in the National Park. The continuous research and conservation work in the Park has allowed for new discoveries of archaeological sites to periodically increase the volume of the graphic collection. Due to the cultural value of its archaeological sites, UNESCO's World Heritage Committee included the Serra da Capivara National Park in the World Heritage List in 1991.

The paintings in the archaeological sites of the National Park are diverse, both thematically and technically, as well as in the way the figures are arranged on the rocky surface. The paintings feature mostly recognizable figures and compositions. In many places it is possible to recognize pictures created at different times, by different human groups.

During an initial organization of the National Park's rock art collection, a preliminary general classification was proposed, based on morphological criteria and on the establishment of a thematic typology guided by techniques and scenography (Guidon 1991). One of the proposed types, designated as *Tradição Nordeste* (Northeast tradition), is dominant in the region's conservation unit and its surroundings. It is composed by figures that are recognizable thanks to the presence of essential

traits for identification, that graphically represent actions or events.

Assorted anthropomorphic, zoomorphic, and phytomorphic figures can also be recognized – and some figures are arranged to represent scenes. The most frequent themes are hunting, dancing, sex, violence, fighting, and scenes depicting rites around a tree (Figs. 2 and 3). The figures address the themes through identifiable postures and gestures. The graphical representation of the action suggests rhythms. Differentiation among grouped figures is made based on the graphic themes and modes of representation used in each situation. The presence of repeated actions performed by human figures in which the represented theme is not recognizable in an emblematic marker that allows characterizing the narrative. Sometimes, the figures display emblematic features similar to conventional signs that reveal encoded information as image attributes (Fig. 4).

The paintings and engravings provide information on the techniques developed and used for its production. The choice of location and the rock characteristics are primary aspects. As seen in a diversity of surviving paintings, there are sites in the National Park that were painted on across millennia by different human groups.

The features of the engraved or painted lines inform us about the types of instruments used to obtain specific graphic effects. These techniques included a range of means, ranging from the body parts– hands and fingers – to instruments made of reeds, cotton, thorns, and stamps made with clay and rubber plant. The paintings also inform us about the composition of paints prepared with pigments and dyes mixed with other elements, thus providing different degrees of robustness. The differences in thickness of the paints enabled the acquisition of distinct textures. Volume effects were also obtained through successive superimposition of paints of different consistencies applied on flat and uniform surface. A broad spectrum of dark hues that created a series of visual effects was obtained by exposing the paints to high temperatures. Physicochemical analyses also revealed the use of saps, blood, and other products of organic origin. High rates of calcium, associated with the presence of painted human bones in graves suggest that the paints' composition also included ground bones. The identification of composition patterns in rock art, allows for the reconstruction of the graphical profiles of the cultural groups to which the authors of these pieces belonged. Such profiles are formed by

Serra da Capivara National Park, Fig. 2 Toca da Extrema – ritual scene around a tree

Serra da Capivara National Park, Fig. 3 Toca Subida da Serrinha I – hunting scene

Serra da Capivara National Park, Fig. 4 Toca do Baixão das Mulheres I – emblematic back to back figure

different and precise graphic attributes, detectable by the way the paintings are done and through the reconstitution of the operative chain of the art production technique. There are numerous components to the graphic profiles, but they appear standardized according to aspects prioritized in each piece of the work. The accuracy of the records outlines these aspects as it singles out differences allowing for the identification of meaningful patterns.

There are indicators of the symbolic theme choices of these human groups. These compositions are recognizable, while the identification of the action theme may not. They are standardized representations of gestures and postures that do not allow for a functional association to an action. Through their frequent repetition, they become emblematic by theme and not necessarily by technique. In the National Park, there is a figure repeated at several sites, composed of two human figures positioned back-to-back. This is present in all stylistic variations through time, suggesting a symbolic value in a cultural horizon (Pessis 2003).

The state of conservation of the paintings depends mainly on the homogeneity of the painted shelter rock and the exposure of the paintings to the

impact of natural agents determined by their positioning on the wall. The National Park covers a geographical area composed mainly by sandstone and conglomerate resulted from the rising of the seabed. The presence of water in the region created a residual surface, which is an amalgam of heterogeneous rock and sediment. Thus, the cortex on the site wall detaches itself more easily, which also suffers the impact of daily atmospheric temperature range.

The paintings of *Tradição Nordeste* (Northeast tradition) are scattered throughout all Northeastern Brazil. Chronologies obtained in archaeological excavations as well as the density of the figures indicate that paintings of this tradition have its origin in the area now known as Serra da Capivara National Park. Between the region of Seridó Potiguar (RN) and the Serra da Capivara (PI), there are sets of paintings with features similar to those of Serra da Capivara. A case of dispersion stands out in the region of Seridó Potiguar (RN) where there are a multiple archaeological sites with paintings of belonging to *Tradição Nordeste* (Martin 2008). Such paintings have specific themes and scenography that suggest a different graphic development compared to the Serra da Capivara National Park. They appear to have some overlapping features that suggest a close cultural relationship.

Future Directions

Dating prehistoric rock art is still a complex and vague task. With the exception of some sites kept in isolation, the dating of paintings is relative. The action of natural agents on the painted or engraved walls, over the millennia, affects the results of physicochemical analyses on samples altered by sedimentary deposition. In the National Park's sites, the effects of the detachment of rock cortex with paintings are noticeable. Dropped painted fragments are deposited on the sediment, and are retrieved in the course of archaeological excavation. Dating the sediment in which these fragments were collected indicates the moment the detachment happened, thus providing an (minimum) estimate of the dating of the paints.

Natural and anthropogenic agents destroy numerous rock art sites each year. To declerate this process, the sites within the National Park are being systematically monitored using laser scanning which is the most accurate technical resource available. Only the intensive photogrammetric recording of rock art sites will allow us to save this heritage from eventual total loss.

Service Learning and Public Archaeology

Mary Ann Levine
Department of Anthropology, Franklin and Marshall College, Lancaster, PA, USA

Introduction

Public archaeology has experienced exponential growth since the term was coined in 1972 in the context of legislation designed to conserve the

archaeological record in the public interest. Public archaeology in the twenty-first century is an increasingly diversified pursuit in which professional archaeologists, employed in a variety of settings including both heritage management agencies and academic institutions, collaborate in a multitude of ways with a diverse array of community partners. Professional archaeologists in academic settings are uniquely positioned to extend the scope of public archaeology through community service learning where students in course-based, credit-bearing experiences actively engage with the public in real-world settings on projects of local interest emanating from the community itself. By integrating learning, service, and research, students develop deeper understanding of course content as they link theory with practice, become sensitive to both community needs and assets, and express greater interest in civic engagement. As a high-impact instructional practice, community service learning has the potential to provide students engaged in archaeological practice with a transformative educational experience that forges relationships with both faculty members and the surrounding community.

Definition

Service learning is a form of experiential learning where students gain knowledge through active participation in an organized service activity coordinated with the community that affords students the opportunity to critically reflect on their service experience (Bringle and Hatcher 1999). Service learning is a pedagogical initiative undertaken by institutions of higher learning to better integrate liberal arts colleges as well as public and private research universities into their surrounding communities through faculty and student collaborations with community members. As the needs of the community shape the nature of the service project, service learning necessitates engagement between faculty and the community prior to the commencement of any work. Faculty, students, and community partners collaborate within a research framework in which the community benefits from the resources offered by the college and the students profit by developing a greater sense of social responsibility. Most colleges and universities now include service learning as part of their curriculum. Service learning is one way to reintroduce students to the idea that they are part of a social world beyond their immediate campus environment. Service learning is thus distinguished by its pedagogical underpinnings, and academic archaeologists have incorporated this powerful teaching method into the archaeological curriculum since the early 1990s (Baugher 2007).

Examples

Archaeological applications of service learning have engaged with a wide range of community partners including museums, historical societies, historic preservation groups, elementary schools, churches, and cemetery associations and have had as their focus Mississippian-era Native American mounds (Homsey et al. 2012), seventeenth-century forts (Nassaney 2004), eighteenth-century Spanish missions (Mendoza 2009), and nineteenth-century African-American sites (Levine et al. 2005; Levine and Delle 2009). Service-learning experiences have been successfully integrated into all levels of the archaeological curriculum from introductory courses (Levine and Delle 2009) to graduate-level seminars (Chilton and Hart 2009). Summer field schools are also common sites for integrating service-learning pedagogy into archaeological practice (Nassaney 2009). Service learning can define an entire college course, or it can be a component of a regular academic course. Christopher Matthews' (2011) course, "Archaeology in Montclair," is an example of a class completely dedicated to affording students the opportunity to participate in documentary and field-based research to assist the Montclair Historical Society's mission to promote the preservation and study of local history. Service learning is a flexible pedagogy and, as McLaughlin (2009: 66) aptly points out, is "not a one-size-fits-all teaching strategy." However it is deployed, service learning is a powerful pedagogy

that can result in unanticipated outcomes long after the service activity is over. Take, for example, Mehta's (2016) archaeological field school at Carson Mounds. As the field site is located in a region marked by extreme poverty, Mehta designed a service-learning activity with his adopted community that would support efforts to offer educational programming to underserved youth. Underprivileged high school students from the Griot Youth Program joined the Carson Mound field school in a collaborative field day experience, and college students assisted their partners with academic programming. One field school student was so moved by the service experience that he organized a benefit concert to raise funds for the Griot Youth Program long after the field school had ended.

The Thaddeus Stevens and Lydia Hamilton Smith public archaeology project can serve as an example of how service-learning pedagogy can be incorporated into a college-level "Introduction to Archaeology" course. The public archaeology program through which this service-learning project developed began when the Historic Preservation Trust of Lancaster County requested that James Delle and I undertake an excavation at the former homes of Thaddeus Stevens (1792–1868), one of Pennsylvania's most famous radical politicians, and Lydia Hamilton Smith (1813–1884), his African-American housekeeper and companion. Thaddeus Stevens was an influential congressman who was a leader of the Radical Republicans who advocated for universal public education, opposed the death penalty, and agitated for the abolition of slavery and equal rights to emancipated blacks. He was a primary author of both the 13th and 14th Amendments to the US Constitution. Lydia Hamilton Smith served as housekeeper for the bachelor Stevens and became a pioneering businesswoman by owning and renting various properties. The houses were in imminent danger of complete destruction to make way for a new convention center-hotel complex in Lancaster, Pennsylvania. The historic preservation laws in the state did not explicitly require that archaeology be done at that site as no demolition or construction funds came from the federal government. Archaeological excavations unearthed evidence of many episodes of Lancaster's history including evidence that a cistern at the Stevens and Smith site had been modified to be a hiding place to harbor fugitive slaves escaping north during the antebellum period (Levine and Delle 2009).

The Stevens and Smith project was undertaken with an explicit commitment to making the project accessible to the community (see Levine and Delle 2009 for examples of our community outreach efforts). Once the excavation was over, we received many requests from various school groups to provide presentations on Stevens and Smith, archaeology, and the Underground Railroad. We responded by partnering with the local inner-city school district to have the undergraduate students enrolled in "Introduction to Archaeology" at Franklin and Marshall College to provide presentations designed to expose elementary and middle school children to archaeology in general, to the rich archaeological heritage that lies beneath their city streets, and to the historical significance of Thaddeus Stevens and Lydia Hamilton Smith. For their service-learning project, college students brought a traveling kit of artifacts from the excavation, large-scale photos of the excavation, and an archaeological toolbox of equipment used on a typical dig. Schoolchildren learned about the practice of archaeology, principles of stratigraphy, interpreting historic artifact assemblages, nineteenth-century urban life in Lancaster, and the role Stevens and Smith played in the Underground Railroad. After several iterations of this class, nearly 40 college students had engaged an estimated 1500 schoolchildren with the Stevens and Smith archaeology project and issues of race, slavery, and emancipation. Reflection journals kept by my students report that the experience resulted in understanding course content on a more profound level because they taught it and fostered increased interest in civic engagement. Their interactions with the schoolchildren promoted personal growth and served as a catalyst to reflect on their own position and role in society. As archaeology is not a part of most curricula prior to college, the presentation filled an

educational void in the community, and schoolchildren expressed considerable enthusiasm for learning about archaeology, handling artifacts, and hearing about their city's heritage.

Future Directions

Archaeological applications of service learning can productively extend the current contours of public archaeology, and an increasing number of faculties have embraced service learning. Although it is far from being a permanent fixture in archaeological pedagogy, some practitioners have developed community service-learning projects that have grown and developed over the course of more than a decade. The Fort St. Joseph Archaeological Project is one example of service-learning pedagogy that is anchored in a robust and long-term partnership (Berliner and Nassaney 2015). Advocates of service learning acknowledge that there are challenges that come with retooling our pedagogical approaches but contend that the benefits of service learning far exceed any difficulties (Baugher 2009; Nassaney 2009, 2012). Implementing a service-learning project can be time-consuming and does create additional responsibilities for faculty. Untenured faculty may be concerned that the extra effort required to create service-learning opportunities for their students will not be rewarded. Nevertheless, many colleges and universities are providing the infrastructure to facilitate service-learning partnerships. As archaeological practice in the twenty-first century continues to reach out and acknowledge multiple stakeholders in diverse communities, the prospects for service learning are promising.

Sesame: Origins and Development

Alison Weisskopf and Dorian Q. Fuller
Institute of Archaeology, University College London, London, UK

Basic Species Information

Sesamum indicum L. (syn. *S. orientale* L.) Pediliaceae. The name sesame is derived from the Late Babylonian *shawash-shammu*, "oil seed" or plant oil, via Phoenician to Greek *sesamon* to Latin *sesamum* (www.etymonline.com). Sometimes sesame is known as gingelly from the Hindi *gingli*, which is from Arabic *jaljala*, the meaning referring to the sound of the seeds rattling within the capsules (http://www.oed.com). Sesame has one of the highest oil contents of any seed, approximately 50% oil and 25% protein. The meal left after pressing for oil can be used as a high-protein animal feed. The oil can survive for long periods before going rancid due to the presence of antioxidants, sesamol and sesamolin (Oplinger et al. 1990). There are many recorded medicinal uses (Bedigian 2004).

Sesame is an oilseed crop that is self-pollinating and annual but occasionally perennial (Bedigian 2004). The four-segmented seed capsule is grooved, is rectangular in section, and ranges from 2 to 8 cm long/0.5 to 2 cm wide. Once ripe the seed capsules split open to release the seed – "open sesame." The ovate flattened seeds range from 3 to 4 mm long/2 mm wide/1 mm deep and are thinner at the hilum end. The testa is slightly raised and reticulate (Fig. 1), and this is especially marked in wild sesame (*Sesamum* spp.). The seeds are usually white/yellow but can be brown or black. Sesame can be grown from seed in warm climates. Although drought resistant, it cannot tolerate frosts, waterlogging, or salinity (Oplinger et al. 1990; van Wyk 2005). Sesame takes between 70 and 120 frost-free days to mature, and there is morphological variation between plants (Bedigian 2004). While tolerant

Sesame: Origins and Development, Fig. 1 Scanning electron micrograph of typical domesticated *Sesamum indicum* seed

Sesame: Origins and Development, Fig. 2 Map showing the approximate modern wild range of *Sesamum indicum* subsp. *malabaricum* and the distribution of archaeological reports, with an enlarged focus on the India subcontinent. (Map updated, modified from Fuller 2003). Sites numbered *1*. Qasr Ibrim, *2*. Luxor (Tutankhamun's tomb and Deir el-Medina), *3*. Amarna, *4*. Abu Salabikh, *5*. Karmir Blur, *6*. Bastam, *7*. Gordion, *8*. Deir Alla, *9*. Bahrain, *10*. Miri Qalat, *11*. Sabir, *12*. Thousand Buddha Grotto (Xinjiang), *13*. Myos Hormos, *14*. Malhar, *15*. Imlidh-Kurd, *16*. Sunuwar, *17*. Narhan, *18*. of many growing conditions, sesame prefers well-drained fertile soils and neutral pH. Its large branching root system can improve poor soil structure. A non-shattering mutation was not found until 1943, so traditionally sesame is grown in small hand-harvested plots. Instead domestication focused on reduction of germination inhibition which is linked to a thinning of the seed, a reduced seed coat architecture, and an increased tendency for seeds to be black (Fuller and Allaby 2010).

There has been debate over the correct taxonomy for cultivated sesame (see Bedigian 2004). Wild sesame taxa are widespread with many wild species in sub-Saharan Africa and fewer in India. Studies of wild populations of *Sesamum* sp. support an origin from the South Asian *Sesamum orientale* L. *var. malabaricum* Nar. (syn. *S. mulayamum Nair*) (Fuller 2003; Bedigian 2004). This is likely to have taken place in the Indus Valley, including the Indian Punjab and parts of Pakistan, although the wild progenitor also occurs down the west coast of the Indian peninsula (Fig. 2).

Timing and Tracking Domestication

Archaeobotanical evidence has been slow to accumulate due to preservational biases against oilseeds like sesame in favor of charred preservation of more robust-seeded species like cereals. Early archaeological evidence for sesame stems from Harappan sites in the greater Indus Valley from the Mature Harappan civilization (2600–2000 BCE), including Harappa in Pakistan; Miri Qalat in the Markan region of Pakistan; Farmana in Haryana, India; and Kanmer in Saurashtra, Gujarat, India (Tengberg 1999; Weber et al. 2011; Pokharia et al. 2011). This is in keeping with a domestication in the Indus region sometime prior to 2500 BCE, although this might also have occurred to the east in Saurashtra, Haryana, or somewhere in between. There is a suggestion that starch grain evidence collected from a tool by A. Kashyap from Bagor, a preceramic Mesolithic site (4000–5000 BCE), has evidence for exploitation of possible *Sesamum* (cf. Shinde 2008); if verified this would suggest wild exploitation, although this site may not be within the wild distribution and towards the top of the Indian peninsula. Historical linguistic data suggest sesame was known to early Dravidian speakers, prior to knowledge of many other crops (Fuller 2007), which fits with a Saurashtran origin.

There is limited evidence for the early spread of sesame. First it was taken westward to Mesopotamia by 2300–2200 BCE (Fuller 2003; Bedigian 2004). There are numerous reports from the second millennium BCE across India (Fuller 2003). After 1400 BCE sesame is known from Bahrain and ancient Egypt, famously among seed finds in Tutankhamun's tomb (de Vartavan and Asensi Amoros 1997). In the Late Bronze Age (c. 1300 BCE), sesame is apparently mentioned in early Greek Linear B texts, although archaeobotanical finds from this period and region are so far lacking (Kroll 2000). Recently finds from Southern Thailand indicate the presence of sesame in the last few centuries BCE (C. Castillo, personal communication). There are also Roman era finds from the port of Myos Hormos (Quseir al-Qadim) on the Egyptian Red Sea coast (van der Veen 2011). Elsewhere in Yemen and Anatolia, sesame appears in the early first millennium CE (Fig. 2).

In China, although sesame is known from written sources going back about 2,000 years to the Han dynasty, archaeobotanical finds have been elusive. The only positively identified sesame comes from a 700-year-old Buddhist monastic cave in Xinjiang province, as well as reports from similarly aged or slightly older graves (Qiu et al. 2012). A few earlier claims for sesame in central China are mostly misidentifications (Qiu et al. 2012).

Sex Assessment

Soren Blau
Department of Forensic Medicine, Victorian Institute of Forensic Medicine, Monash University, Southbank, VIC, Australia

Introduction

The estimation of the sex of a deceased person from an analysis of skeletal remains is one of the first procedures undertaken by anthropologists and osteologists as the sex of a person affects other analyses such as estimation of ancestry and age at death (e.g., Rowbotham 2016). In forensic cases, the estimation of sex is pivotal in contributing to the identification of unknown bodies as determining whether the individual is male or female halves the number of possible matches.

Definition

The sex of an individual is a biologically determined variable and differs from the gender of a person which is a social construct (e.g., Agarwal and Wesp 2017).

Key Issues

Age of the Individual

There has been considerable research undertaken on estimating the sex of an individual from the

examination of juvenile skeletal remains (e.g., Bilfeld et al. 2013; Cunningham 2014). However, estimating the sex of individuals who have not reached puberty is limited because in most cases the degree of sexual dimorphism in the juvenile skeleton is not distinct enough to allow accurate methods for evaluation of the sex, particularly for forensic cases.

Nonmetric Methods

In cases of adult skeletal remains, the estimation of sex can be undertaken using a visual examination of nonmetric traits, that is, the morphology (shape) of sexually dimorphic parts of the skeleton (Phenice 1969). Many studies have demonstrated that the pelvis is the most reliable area of the body to evaluate sex (cf. Spradley and Jantz 2011). The overall shape of the pelvis (broader in females than males as a result of the need for childbirth), the angle of the sciatic notch, the subpubic angle, the subpubic concavity, the shape of the ischiopubic ramus, the presence or absence of the ventral arc, and the shape of the sacrum are all examined to evaluate the sex.

After the pelvis, the skull is the most sexually dimorphic structure in the body. On the skull, the morphology of the nuchal crest, mastoid process, supraorbital ridge/glabella (Graw et al. 1999), mental eminence, flexure of the ramus, and size of the palate and teeth (Jones Haun 2000) are assessed. In general, within different populations, male skulls illustrate features that are more robust and muscular than those of females.

Metric Methods

In addition, metric criteria in the form of indices (comparison of measurements) and/or discriminant functions (uni- or multivariate statistics) can be used in sex evaluation (e.g., Robinson and Bidmos 2009). A number of skeletal measurements can be taken that are indicative of the sex of an individual. The most commonly used include the ischiopubic index (e.g., Krogman and Iscan 1986), the discriminant function cranial sexing method of Giles and Elliot (1963) and Giles (1970), and the diameters of the articular ends and/or the midshaft circumference of long bones (Krogman and Iscan 1986). Research has been undertaken to attempt to evaluate the sex from measurements from various parts of the body including vertebrae (Snodgrass 2004), ribs (Wiredu et al. 1999), femur (Stojanowski and Seidemann 1999), tibia (Iscan and Miller-Shaivitz 1984), patella (Kemkes-Grottenthaler 2005), clavicle (McCormick et al. 1991), humerus (Rogers 1999), radius (Berrizbeitia 1989), ulna (Purkait 2001), feet (Introna et al. 1997), and metacarpals (Burrows et al. 2003). The decision about which method to use is influenced by the condition and preservation of the skeletal remains and the age of the individual.

Context and Disease

The circumstances of a burial are also important to assess when evaluating the sex of an individual. For example, recognition of fetal bones in the abdominal area will indicate the individual was female. Further, some diseases which affect the skeleton are sex-specific (Ortner 2003).

Molecular Methods

Finally, the ability to extract DNA from skeletal remains of varying ages and preservations has meant that DNA analysis has also been used to determine the sex of both juvenile (e.g., Townsend 2001) and adult (e.g., Gibbon et al. 2009; Thomas et al. 2016) skeletal remains. "Genetic sex identification is done through the isolation and amplification of a gene or genes in the sex chromosomes (X and Y). The most commonly used sex determining genes are the sex determining region Y (SRY locus), zinc finger protein (ZF) and the amelogenin (AMEL) genes" (Bidmos et al. 2010: 4). While extraction techniques become increasingly less invasive, molecular approaches to the determination of sex are nonetheless destructive and expensive. In addition, the success of DNA analysis is influenced by the relative preservation of the remains and the ability to recover DNA.

Categories and Population-Specific Approaches

Skeletal dimorphism occurs as a result of the differences in hormone levels between men and women. As a result of individual variation (i.e.,

Sex Assessment, Table 1 Categories used in the determination of sex

Category	Comment
F	Definitely female
F?	Possibly female
A	Ambiguous (shows neither male nor female characteristics)
M?	Possibly male
M	Definitely male
?	Unable to comment on the sex due to poor condition or preservation of the skeletal remains

gracile males and robust females exist), it is not always possible to provide a definitive answer. Consequently, forensic anthropologists and osteologists use a range of categories to describe the sex of the individual (Table 1). In addition, population-specific variation (e.g., in size) is known to influence the evaluation of sex from the skeleton (Manthey et al. 2017; Ubelaker and DeGaglia 2017). For this reason, population-specific reference collections are essential for developing standards to assess sexual dimorphism within populations (e.g., Smith 1997; Robinson and Bidmos 2011; Klales and Cole 2017; Mahakkanukrauh et al. 2017).

Accuracy

If the entire skeleton is present and well preserved and both morphological and metric methods can be employed, the sex of an individual can be estimated with nearly 100% accuracy. If only the pelvis is examined, accuracy is said to be 95% and decreases as less skeletal elements are employed (Krogman and Iscan 1986; Duric et al. 2005).

Future Directions

As technology advances and debate continues about the impact on preservation of studying and handling collections of archaeological human skeletal remains, there has been a shift to the virtual analyses of skeletal remains. Virtual evaluation of sex has been demonstrated to be as accurate as examining the physical bone (e.g., Decker et al. 2011).

Shackel, Paul

Paul A. Shackel
Department of Anthropology, University of Maryland, College Park, MD, USA

Basic Biographical Information

Paul Shackel received his Ph.D. from the State University of New York at Buffalo in 1987. After completing his dissertation, Shackel worked for a short time for the Historic Annapolis Foundation coordinating various archaeological projects in the historic district of Annapolis. In 1989 he entered the National Park Service and worked for over seven years at Harpers Ferry National Historical Park. He has served as principal investigator for several projects with the National Park Service in the National Capital Region. Shackel became an Assistant Professor at the University of Maryland in the Department of Anthropology in 1997. In 1999 he became an Associate Professor, and in 2002 he was promoted to Full Professor. He also served as chair of the department.

Major Accomplishments

Dr. Shackel's dissertation research in Annapolis, Maryland, examined archaeological materials, probate inventories, and the development of etiquette books to show the development of a modern discipline. This new behavior helped to create separate and segmented places as well as the development of the individual. Much of this new behavior can be found in the development of Renaissance ideals that helped to standardize behavior necessary for industrial capitalism.

His work at Harpers Ferry National Park focused on the Harpers Ferry Armory, which developed as one of two US installations for the manufacturing of arms for the US military. The armory initially developed with craft manufacturing, whereby the gunsmith made the entire gun, lock, stock, and barrel. However, in the 1820s, the War Department placed John Hall in Harpers Ferry where he perfected the process of interchangeable parts in gun manufacturing. With the implementation of wage labor in the 1840s, the landscape became more formal as new surveillance techniques were implemented. Workers appear to have damaged an increasing number of products and machinery. Families tended gardens, raised pigs, and purchased material culture that was fashionable when they had control over their means of production.

In 2002 Dr. Shackel embarked on a cooperative project with several other institutions to document the founding the settlement of New Philadelphia, a town established by a freed African American in 1836. Frank McWorter and his family sold town lots to whites and blacks and used the proceeds to purchase family members out of slavery. Based on census and deed records, it appears that both White families and Black families lived next to each other. The archaeology shows that material culture differences between households of different ethnic backgrounds is indistinguishable. The archaeological record is more of a reflection of class rather than ethnic background.

Beginning in 2009, Shackel began exploring issues of race in the anthracite region of northeastern Pennsylvania. In the 1880s and 1890s, people of Slavic and Italian backgrounds migrated to this region, and they were treated poorly by their employers and their established

neighbors whose families migrated here several generations earlier. The new immigrant spoke a different language, dressed differently, and had different customs. Lattimer Mines is the site of one of the most deadly labor massacres in US history, although the event has disappeared from the national public memory. Archaeology located the place of the massacre, and work is currently being undertaken at domestic sites in this coal town. The archaeology team notices parallels between the treatments of the historic immigrant with the new Latino immigrants that now make up a significant proportion of the contemporary community's population.

Manoj Kumar Singh
Department of Anthropology, University of Delhi, Delhi, India

Basic Biographical Information

Govardhan Rai Sharma was born on 13 August 1919 in a rural family of Ghazipur district in Eastern Uttar Pradesh. After his primary education in the village school, he shifted to Allahabad where he had all his subsequent school and university education. G.R. Sharma was a brilliant student throughout and passed his M.A. in History in 1942, securing a first division and standing first in order of merit. It was customary in those days for the above-average students of Allahabad University to go in for the civil services. Nationalist to the core and taking active part in the Quit India Movement, G.R. Sharma shunned the very idea of serving under an alien government. Instead he chooses the teaching profession, joining the Allahabad University as a Lecturer in history in 1944.

G.R. Sharma was appointed as a Professor in 1958 in Allahabad University, remaining there till his retirement in 1981, as a Head of the Department. He was appointed Advisor, Archaeology and Museum, of the Uttar Pradesh Government. Sharma was a Co-director of the Indo-Soviet Commission for cooperation with UNESCO. Sharma was an active member of the Central Advisory Board of Archaeology for well over 20 years. Sharma was also a member of the Indian Council of Historical Research and the National Commission for the History of Sciences. Sharma died on November 11, 1986 (Fig. 1).

Major Accomplishments

G.R. Sharma remained in the archaeological research for over three decades. His entry in the field in the year 1949 was itself an event of far-reaching significance for Indian Archaeology. When in that year Allahabad University, under his direction, began archaeological excavations at the famous site of Kausambi, a new era in archaeological research had been ushered in. This continued until 1966. Sharma's major task in the fifties was introducing archaeology as a subject in the university's teaching and research program. This task is by no means easy even today, and one can imagine how difficult it must have been 30 years back. Sharma had to face an unsympathetic Head of the Department, a hostile Vice-Chancellor, and a totally insensitive state government, a situation almost tailor-made to break the nerves of any ordinary persons. Overcoming various odds coming in his way, he forged ahead to build, nurture, and develop a strong Department of Ancient History, Culture and Archaeology in Allahabad University. In recognition of work done by Sharma and his colleagues, the Allahabad University Department of Ancient History, Culture and Archaeology was brought under the UGC Special Assistance Program which besides creating an adequate infrastructure of archaeological field research also helps many of his younger colleagues to improve their careered prospects.

With the help of A. Ghosh, the then Director-General of the Archaeological Survey of India, G.R. Sharma went on to make discovery after discovery at Kausambi, which was against the wish of K.M. Munshi, the then Chancellor of Allahabad University. His initial digging at the spot near the Asokan Pillar brought to light a textbook sequence of the early historical period. This was followed by the spectacular discovery of Ghositarama monastery dating back to first-second century CE.

The Lower, Middle, and Upper Paleolithic remains of the Belan valley with a rich haul of remarkable faunal finds, the Mesolithic burials of Sarai Nahar Rai and Mahadaha, and the Neolithic settlements of Kaldihwa are some of his significant achievements in this area. It was indeed G.R. Sharma's brilliant insight that led him to achieve a major breakthrough in the identification of Mesolithic settlements in this area.

It is largely to the credit of G.R. Sharma and his colleagues that southern Uttar Pradesh is now firmly on the Stone Age map of the subcontinent. The last 15 years of his career was devoted almost exclusively to researches in the Stone Age Archaeology of the region. The archaeological discoveries made by the Allahabad University under his leadership have added very significantly to our knowledge of India's past. And the archaeological findings are deposited in the Allahabad University museum.

In recognition of his work, Professor Sharma was invited by the British Academy to deliver lectures at the Universities of Cambridge, Oxford, and Southampton and Institute of Archaeology

London. Professor Sharma singly and jointly authored several books and articles incorporating the results of his fieldwork. Notable among them are *Excavations in Kausambi* (Sharma 1960), *Reh Inscriptions of Menander and the Indo-Greek Invasion* (Allahabad, 1980), and *Excavation at Mahadaha* (Sharma et al. 1980). He also coauthored with his colleagues in the *University Beginning of Agriculture and Prehistory of History*, and with Desmond Clark as the coauthor, he published *Palaeo-environment and Prehistory of the Middle Son Valley*. Professor Sharma also wrote books in Hindi. From his last publication entitled *Bharatiya Sanskrit – Puratattvika Adhara* (Delhi, 1984) which can serve as a model of writing on Archaeology in Hindi.

Sheep: Domestication

Jennifer R. S. Meadows
Science for Life Laboratory, Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden

Basic Species Information

Sheep, *Ovis aries*, (Mammalia, Artiodactyla, Bovidae, Caprinae) are a highly versatile and adaptable species. From their domestication in the Fertile Crescent, approximately 11,000 years ago, sheep now span the diverse terrains of each inhabited continent where they are exploited for a variety of uses including the production of food (milk, fat, meat) and clothing (skin, wool) (Dwyer 2008). Selection based on environmental tolerance, behavioral, and commercial traits has led to the development of more than 1,400 breeds. These designations are traditionally based upon morphology (e.g., coat color, fleece, and carcass conformation, Fig. 1). Sheep weigh between 25 kg and 160 kg depending on breed, and display significant sexual dimorphism, with males often ~40–50% larger than females (Dwyer 2008). The key adaptations since domestication have included the selection for thicker wool coats that do not molt (hair sheep are an exception), and an increase in the number of polled breeds. Members of both sexes can either be horned or polled (Fig. 1). Sheep are reproductively mature at 4–8 months of age, gestation occurs over 5 months, and individuals can be expected to live for 10 or more years (Dwyer 2008).

Due to their similar sizes and shared geographic range, it is difficult to use bone

Sheep: Domestication, Fig. 1 Naturally occurring phenotypic variation within a single breed of *Ovis aries*, the Icelandic sheep. This breed demonstrates a range of color morphs from black spotted (**a**) to full black (**b**) and full white (**c**) as well as the full complement of ornamentation, horned (**a**, **c**), polled (**b**), and the unusual four horned sheep (**d**). (Image credit F. Imsland)

morphology to distinguish between ancient sheep and goats. The zooarchaeological record suggests sheep were domesticated in the northern Levant (a large area of the Middle East including modern Israel, Lebanon, Syria, and Turkey, Fig. 2) during the Pre-Pottery Neolithic (PPN), and subsequently transported south in the mid to late PPNB, toward the end of the ninth millennium BP (Haber and Davan 2004). Neolithic farmers are also thought to be responsible for the transport of sheep north to Europe by approximately 7000 BCE, while demographic profiling of the fossil record has dated the expansion of sheep south into Africa and east into Asia to 6000 BCE and 3000 BCE, respectively (Dwyer 2008; Gifford-Gonzalez and Hanotte 2011). There is ongoing debate with regard to which wild sheep species were domesticated to form *Ovis aries*, how many times this process occurred, and to what extent subsequent introgression of wild animals has augmented modern domestic sheep.

The current natural geographic range of wild sheep relative to the Fertile Crescent is illustrated in Fig. 2. Wild sheep are divided into three classes: pachyceriforms (*O. dalli*, *O. canadensis*, both $2n = 54$, Northern America; *O. nivicola*, $2n = 52$, Northern Russia), argaliforms (*O. ammon*, $2n = 56$, central Asian highlands), and moufloniforms (*O. vignei*, $2n = 58$, Aralo-Caspin basin; *O. orientalis*, $2n = 54$, Iran, Armenia, Turkey; *O. musimon*, $2n = 54$, Europe). Based on overlapping cytogenic and geographic data, *O. orientalis* has been suggested to be the progenitor of domestic sheep (*O aries*, $2n = 54$). Unraveling the genetic contribution of other *Ovis sp.* to *O. aries* has been complicated, however, by known

Sheep: Domestication, Fig. 2 Natural global distributions of the seven wild *Ovis species* relative to the center of domestication, the Ancient Levant or Fertile Crescent. *Ovis orientalis* is the proposed progenitor of domestic sheep, *Ovis aries*, although *Ovis species* are known to interbreed where their geographic ranges overlap. Distributions are adapted from the IUCN Red List of Threatened Species. (Image credit D. Meadows)

fertile cross-species hybridizations which can result in odd numbered karyotypes (Bunch et al. 2006). *O. musimon* is considered a feral derivative of early domestic sheep.

More recently, genetic evidence following maternally (mitochondrial) or paternally (Y-chromosomal) inherited data has been used in attempts to elucidate the process of domestication. In domestic animals with controlled matings, a small number of males are often responsible for a disproportionate number of offspring. Genetic data focused on the Y-chromosome suggests two patrilines in domestic sheep, one with a possible European origin and the other a less restricted distribution (Meadows and Kijas 2009). The female mediated picture from mitogenome data has revealed five distinct matrilineages (A-E) that diverged before domestication (Meadows et al. 2011).

Each of these five signatures is present in modern domestic sheep sourced from the Near East, but the frequency with which they occur together decreases with distance away from the center of domestication (Meadows et al. 2011). To date, only *O. musimon* has been shown to share a matriline (B) with domestic sheep in keeping with its classification as a feral domesticate (Meadows et al. 2011). Global analyses of modern domestic sheep have shown matrilineages A, B, and C to be the most common. Studies of ancient DNA taken from sites spanning Bronze Age China demonstrate that A was originally predominant and that B may have been introduced through later trade with the West (Cai et al. 2011). A similar study using diverse breeds of modern domestic sheep calculated that matrilineages A and B expanded at the same time into Europe from the Near East via the Caucasus (~9000 BCE), and that matriline C was introduced ~3,000 years later (Tapio et al. 2006).

Autosomal data paired with archaeological finds have been used to suggest two distinct entry points for thin and fat tailed sheep into Africa. Thin tailed sheep are thought to have arrived first, entering overland from the Levant and spreading west (tomb paintings,

3100–2613 BCE). Fat tailed sheep appeared later in recorded history and dispersed south past the horn of Africa to the continental cape (first depicted 1991–633 BCE) (Gifford-Gonzalez and Hanotte 2011). Autosomal data (endogenous retroviruses) has also revealed that the global colonization of sheep breeds occurred in waves. Improved breeds were shown to replace their primitive counterparts in a pattern of migration which followed that of initial domestication, i.e., from the Fertile Crescent into Europe and Africa, followed by a later phase east across Asia (Chessa et al. 2009). No signature of extant wild introgression has been recorded.

The ability of sheep, *Ovis aries*, to adapt to a range of climatic and dietary extremes, combined with their specialized production traits and ease of transportation, has made this ruminant one of the most valuable domestic animals to man. As access to the past and current ranges of wild sheep increases, archaeological and genetic studies will continue to combine in an effort to elucidate the complex history of sheep domestication.

Shell Middens and Coastal Archaeology in Southern South America

Atilio Francisco Javier Zangrando
Laboratorio de Antropología, Centro Austral de Investigaciones Científicas (CADIC – CONICET), Ushuaia, Tierra del Fuego, Argentina

State of Knowledge and Current Debates

Introduction

Shell middens appear in many coastal environments of southern South America. They are normally called "concheros" or "conchales," in Argentine and Chilean coasts, and "sambaquis," in southeastern part of Brazil. These cultural accumulations are shell-bearing middens which can vary in size from a few centimeters to approximately 30 m high and where shell is the major constituent of the sediment matrix. Proportions of

sediments, shell, and cultural inclusions and features vary. Different kinds of activities are represented in those archaeological contexts. Features of dwellings, distributions of artifacts, and animal remains indicate domestic activities. Other shell-bearing middens have been represented as campsites or processing stations. These deposits also served as mortuary contexts all around the coasts of southern South America. They were even used as formal places for mortuary activities, accumulating a large number of human remains in some regions. Visibly, the huge diversity in properties, function, and processes of formation do not appear at a same area. However, research from different coastal settings of southern South America and from different academic traditions agrees that shell-bearing middens, independently of the scale of their formation, are noteworthy features in the landscape which persuade humans to the reuse them.

This essay focuses on concepts and methodological approaches from the Southern Cone. It is a geographic region composed of the southernmost areas of South America, south of and around the Tropic of Capricorn (Fig. 1). Shell mound formations appear in different aquatic environments of that area, but this paper is going to refer to those located in coastal marine environments. Those deposits are present with variable frequency along the littoral regions of southern South America, but not continuously in all settings. It is also remarkable that shell mound formation occurred in some specific coastal locations during the Pleistocene-Holocene transition. Nevertheless, these deposits are significantly more abundant after sea level was established about 7000 to 6000 years ago.

In the Southern Cone, shell midden formations are associated to forager societies with aquatic-orientated subsistence but with diverse

Shell Middens and Coastal Archaeology in Southern South America, Fig. 1 Southern Cone and geographic references mentioned in the text

S

foraging, mobility, and social patterns. In the southeastern coast of Brazil, the sambaquis are mainly identified as mortuary monuments within regional settlement systems of complex fisher-gatherers and hunters. Further south in the Atlantic façade, shell middens indicate the use of coastal environments and its resources by terrestrial hunter-gatherers through alleged movements between the Patagonian coast and the hinterland. Shell midden formations in the southwest coast of South America represent the settlement pattern of marine hunter-gatherers. In sum, shell midden research in the Southern Cone allows one to explore the human-sea relationship at different spatial and temporal scales while concerning diverse subjects in human behavior. Next, this essay provides an overview of the applied concepts and methodological approaches on the matter.

Shell Mounds as Monumental Constructions

Sambaquis is a term that derives from the Tupi language referring to the shell mounds distributed along the coasts of Brazil (Gaspar et al. 2008). These cultural deposits have been more intensively studied between the states of Espirito Santo and Rio Grande do Sul, approximately between 18° and 32° south. Although sambaquis can occur in a substantial variety of environmental settings, including marine ridges, outcrops, dunes, and inland locations faced to large bays, they are mainly located in highly productive bay and lagoon ecotones, which support mangrove ecosystems (Wagner et al. 2011). The sambaquis significantly vary in size and morphology. In fact, this term can refer to small deposits of shell layers, archaeologically dense sequences of shell and sand layers, to huge shell mounds of 50 m high with horizontally and vertically complex stratigraphy (Gaspar et al. 2008, Fig. 2). Proportions and properties of cultural inclusions and features are also highly variable; particularly distinctive are the clusters of human burials. While the smaller shell mounds with less complex stratigraphy may represent campsites, most others with monumental sizes and complex stratigraphy clearly served mortuary functions (Gaspar et al. 2008).

Shell Middens and Coastal Archaeology in Southern South America, Fig. 2 Sambaqui: the person on the top evidences the monumental size of these shell mounds

While chronological information from sambaquis denotes continuity from the early to the late Holocene, most of the radiocarbon data is concentrated between 4000 and 2000 BP (Lima 1999; Gaspar et al. 2008; Wagner et al. 2011).

Between the states of Santa Catalina and Rio de Janeiro, the archaeological record is consistent with marine- and lagoon-orientated foraging activities. Artifactual assemblages are characterized by adzes and polished axes, fishing net weights, hammerstones, lithic vessels, etc. Fishing net weights commonly present polished, performed, or flaked grooves. Fishing activities are also represented by bone technology as hooks, harpoon points, and needles for producing and maintenance of nets. The presence of adzes and polished axes in the archaeological record is interpreted as indirect evidence of boat production. The most distinctive polished stone technology is, however, the realistic zoomorphic sculptures of fish, birds, and mammals; though they are rare items in the archaeological record, they occur in a wide area containing sambaquis. The zooarchaeological record shows a pattern of exploitation of both marine and terrestrial environments. Ichthyoarchaeological studies conducted at the sambaqui Espinheiros II indicate that croakers (*Micropogonias furnieri*) and perches (*Bairdiella* sp.) were the most represented fish resources inside the Babitonga bay. In more open coastal locations near to this bay, the fish bone assemblages are represented by beltfish (*Trichiurus lepturus*) and barred grunt (*Conodon nobilis*). Shellfish gathering was conducted mostly in bays and mangroves; this activity was focused on bivalves (e.g., *Ostrea* sp., *Anomalocardia brasiliana*, *Modiolus brasiliensis*). The consumption of plants was also inferred from human teeth studies (Wagner et al. 2011: 53), though teeth show almost no caries suggesting a low carbohydrate intake (Gaspar et al. 2008: 323).

Further south, at the state of Rio Grande do Sul (between the 32° and 29° south), sambaquis become smaller and are located at the plateaus on the top of marine ridges between coastal lakes and the Atlantic coast. Since the climate is more temperate in this area, mangrove ecosystems are less abundant. Radiocarbon data indicate that occupations occurred later, between circa 3500 and 1100 BP. The artifact assemblages include polished axes, polishers, fishing net and lines weights, lithic vessels, hammerstones, and flakes. Zooliths were also recovered in shell middens of this area. Bone tools are rare, but a diverse technology made on this material was identified for the region: needles and projectiles points from mammal bone, hooks and pendants from fish bone, and spatulas from cetacean bone. Clam (*Mesodesma mactroides* and *Donax hanleyanus*) represents the main shellfish resource and constitutes the primary shell component in the site formations.

During the 1980s, under the influence of cultural ecology theory, the repetitive deposits of shells that characterized the sambaquis were interpreted as long sequences of successive occupations of foragers. Archaeological studies at those times were focused on understanding the human subsistence in relation to the environmental conditions, with a strong emphasis on zooarchaeological research. The stratigraphic imbrication between shell deposits and black units with dense assemblages of fish bones observed in some sambaquis promoted arguments of dietary changes in human societies due to environmental changes and overexploitation of shellfish. These changes were related to a fish intensification process as an overall loss in shellfish productivity. However, ichthyoarchaeological studies conducted at the early 1990s demonstrated that fishing was always a predominant foraging activity among those human societies, which led to the conception of the sambaquis as constructive deposits and not as simple accumulations of waste from subsistence activities (Figuti and Klokler 1996; Villagran et al. 2010). These concepts and studies developed in the last 15 years led archaeologists to consider the sambaquis as monumental constructions, showing that these very visible mounds in coastal flat settings were preferred for burials.

Excavations at Jabuticabeira II provided critical information about the monumental sambaquis and mortuary contexts in the state of Santa Catarina, where bulkier shell mounds are located. The stratigraphic sequence of this site is

composed by an imbricated thick shell layers and fine dark levels integrated with organic matter and fish bone remains. Burials are mainly concentrated in these dark layers associated with artifacts and hearth structures. This evidence led to the interpretation of these sectors of the stratigraphy as mortuary units, and the shell deposits were understood as part of a constructive pattern for covering the human bodies (Klokler 2012). The shell layers are primarily composed by clam valves, especially of the species *Anomalocardia brasiliana*. Clam valves would have been intentionally chosen because of their physical properties which allow less fragmentation, create large volumes, and provide a good drainage. At the same time, the light tone of the shells favors the visibility of the mounds (Klokler 2012).

Shell procurement for construction purposes is also another interesting point in the debate. Villagran and coauthors (2010) analyzed two possible arguments about the provenance and transport of the shells. One possible hypothesis is that the procurement of shells was only associated with construction activities, either that the collection was conducted by the exploitation of valves deposited on inactive coastal landforms (marine ridges, paleo-beaches, etc.) or by the exploitation of living mollusc beds. Another possibility is that the accumulation of shell deposits was the product of shellfish consumption, where waste was reworked later for constructive purposes. In relation to the first argument, radiocarbon data from shell and charcoal samples from the same levels show that used shellfish were contemporary to the occupations at the site and not earlier. On the other hand, stable isotope studies on human remains demonstrated the molluscs were not important staples for those populations. Thus, the more likely explanation is that the gathering activities on shellfish were mainly promoted for construction reasons (Villagran et al. 2010). These authors also suggest that this hypothesis can also be used for explaining the formation of the dark layers: the accumulations of fishbone and other zooarchaeological remains could have been reworked and transported to the shell mounds for construction purposes from residential sites. In fact, the difficulty to locate residential sites related to sambaquis would partially be explained by the practice of these recycling activities (Villagran et al. 2010).

There is a general agreement among archaeologists that the mortuary practices that resulted in shell mound buildings should have played a decisive role in social dynamics (Gaspar et al. 2008). In fact, it has been argued that several significant properties of the coastal archaeological record of southern Brazil provide evidence of social complexity (Lima 1999; see also Lima and Lopez Mazz 2000): (a) a human subsistence based on abundant and stable marine resources, which allow low mobility pattern in lagoons and estuaries; (b) an increase in human demography; (c) the construction of shell mounds required an important labor investment and cooperation; (d) artistic expression of sophisticated forms (zooliths); and (e) evidence of long-range ideological exchange by the presence of artifacts of high symbolic value (zooliths) from thousands of kilometers away.

Shell Midden Formations and Human Mobility Patterns in Arid Coasts

Arid coasts are those areas where deserts and steppes meet marine environments. Shell midden formations are directly related to the human use of the interface between those different ecosystems. The southern South America area offers interesting perspectives on the subject (Martínez and Mitchell 2017): the Patagonian and Fuegian coasts connect steppe regions with the Atlantic Ocean (Fig. 3), and the hyperarid Atacama Desert borders with the highly productive Pacific Rim.

Research and excavations conducted on shell middens along these coasts have shown diverse settlement patterns, zooarchaeological assemblages, and material culture allowing archaeologists to identify a highly variable relationship in human-sea-desert interfaces.

The archaeological locality of Taltal in the Atacama Desert in northern Chile presents the most extensive regional sequence in coastal settlements of southern South America, exposing shell midden formations from the Pleistocene-Holocene transition. Mobility and subsistence strategies assessed from this coastal

Shell Middens and Coastal Archaeology in Southern South America, Fig. 3 Steppe and sea: shell mounds in the Lobos Island near to the Deseado River mouth. (Photo: Miguel Ángel Zubimendi)

record display significant variation throughout the Holocene.

Five shell middens associated to rock-shelters are recorded in this region at the mouth of the Cascabeles Ravine. These sites are dated between 11,400 and 10,000 cal. BP and associated to the Huentelauquén cultural complex (Salazar et al. 2015). The functionality of these contexts is still not clear, but shell midden formations were indicated as the main waste accumulation areas related to occupation of the rock-shelters as non-permanent stationary dwellings. It is possible the sites at the Cascabeles Ravine were part of a wide settlement system where household spaces are currently submerged (Salazar et al. 2015). Similar considerations for the Huentelauquén cultural complex were supported from an archaeological context of Los Vilos in the north coast of Chile (Ballester et al. 2012).

Important changes in settlement patterns from the Early-Middle Holocene transition and along the Middle Holocene were inferred from archaeological studies on the Morro Colorado site, which was interpreted as a residential area (Andrade and Salazar 2011; Salazar et al. 2015). This 35-cm-thick shell midden presents several burned layers throughout the stratigraphic sequence, indicating different moments of reoccupation. Importantly, there was recognition of a pit house formation during Middle Holocene occupations, where previous shell midden strata were excavated and removed for preparing housing place (Andrade and Salazar 2011).

After 7500 cal. BP, shell midden formations become more visible in the coastal landscape, with deposits that reach 1–2 m thick. In this context, it was inferred that the settlement pattern is dominated by residential camps and semipermanent occupations (Castelleti 2007; Salazar et al. 2015). However, shell middens of the Middle Holocene do not always present similar dimensions and artifact compositions, indicating diversity in permanence of occupations and activities at the sites. An increase in complexity of settlement and mobility patterns is observed after 5500 cal. BP, which is related to a reduced mobility. Sites appear as more elaborate structures, where mortuary contexts are below households and waste areas (shell middens) are spatially segregated from them. After 4500 cal. BP, a new drastic change in mobility patterns was recorded in the Taltal region: site formations indicate

Shell Middens and Coastal Archaeology in Southern South America, Fig. 4 Mid-Holocene shell middens in the arid coasts of the San Matías Gulf. (Photo: Florencia Borella)

reduced camp sizes and a decrease in the duration of occupations.

Shell middens can be considered geoarchaeological features, by which human involvement contributes to the shape of the landscape, providing a particular physiognomy to coastal settings (Castro et al. 2001; Favier Dubois and Borella 2007). These mounds are not, however, ubiquitous along the coasts. In Northern Patagonia, recent archaeological research (Favier Dubois and Borella 2011) has shown high densities of shell mounds in the north littoral section of San Matías Gulf, while those middens are very scarce on its western coast. The low frequency of shell middens, and the archaeological evidence in general, on the Western coast indicates a marginal use in terms of occupational intensity (Borrero 2004). Mounds at this area have predominantly little thickness, indicating low reoccupation rates of the sites and/or a lesser importance of shellfish for human subsistence in comparison with other coastal areas of Patagonia (Favier Dubois and Borella 2007). The presence/absence of shell middens could also be related to topographic variations (Favier-Dubois and Kokot 2011) or water procurement (Fig. 4). This last factor is critical and, for example, is related to the lack of native human occupations in the coasts of Northern Patagonia since the eighteenth century (Favier Dubois and Borella 2011).

Spatial analysis of shell middens conducted between the San Jorge Gulf and the Deseado River mouth (Fig. 5), at the southern coast of Patagonia, has shown a discontinuous distribution of shell middens (Castro et al. 2003; Zubimendi et al. 2004). This spatial analysis, considering different sizes and types of sites, indicates significant variation in the density of the archaeological record, indicating different mobility strategies in the use of coastal environments during the Late Holocene. In the San Jorge Gulf, shell middens likely represent a more generic use of the coastal landscapes and resources. Southward, on the coastline near the mouth of the Deseado River, the archaeological record shows a more specific use of the littoral environment with more

Shell Middens and Coastal Archaeology in Southern South America, Fig. 5 Shell mound eroded by the wind in the Lobos Island (north coast of Santa Cruz). (Photo: Miguel Ángel Zubimendi)

redundancy in site occupations and more structured use of space. Mortuary contexts (chenques) and residential sites are spatially segregated at the Punta Medanosa archaeological locality (Castro et al. 2001). This settlement pattern would indicate restricted home ranges to coastal settings (Castro et al. 2001; Zubimendi et al. 2004).

Coastal landscapes with high and low shell midden ubiquity alternate along the Atlantic façade of Patagonia and Tierra del Fuego, opening a wide range of hypotheses about coastal use and mobility patterns of hunter-gatherer populations. In the southern Patagonian coast, near to Vírgenes Cape and Cañadon Gap, the low intensity of shell midden formations is related to discontinuity in the use of coastal environments, indicated by a complete lack of reuse and long temporal gaps in the archaeological record (Borrero and Barberena 2006). Stable isotope studies of human remains show that the use of these coastal settings was linked to high mobility, which ranged to inland areas. A different situation is observed immediately across the Strait of Magellan, in the context of the island of Tierra del Fuego, where archaeological localities like Los Chorrillos and Punta María with large formations of shell mounds were identified as "occupational nodes" in a regional archaeological perspective (Borrazzo et al. 2008).

Shell Middens and the Transformation of Coastlines

The analyses of shell midden distributions in coastal landscapes are useful for considering sea level fluctuations and have provided key information for archaeological research in southern South America. Coastal sea level changes from the late glacial period up to the Mid-Late Holocene are intertwined with hunter-gatherer settlements and their relationships with marine and coastal environments (Fig. 6). Questions concerning archaeological surveys (Reyes et al. 2016a), human subsistence patterns (Favier-Dubois and Kokot 2011; Zangrando et al. 2016), and coastal cultural landscapes (San Román 2014; San Román et al. 2016) are involved in this matter.

Holocene sea levels and paleogeographical reconstructions were used in order to conduct

Shell Middens and Coastal Archaeology in Southern South America, Fig. 6 Huge shell mound (the Posa archaeological site) in the Guaitecas Archipelago, in the northern part of the Western Patagonian Archipelago. It is more than 7 m high and presents occupations between 3400 and 1300 cal. BP (Reyes et al. 2016a). (Photo: Omar Reyes)

broad archaeological surveys for exploring poorly known localities in the Chonos Archipelago in the north of the Western Patagonian Channels (Reyes et al. 2016a). In the Strait of Magellan area and the Otway and Skyring Sounds, surveys have revealed strong correlations between the chronologies of archaeological sites and their locations on marine landforms (San Román 2014; San Román et al. 2016; Fig. 7). The spatial distribution of shell middens was therefore organized by three blocks corresponding to different sea level and time periods. These blocks were also correlated with dissimilar cultural materials leading to the recognition of three distinct cultural traditions (San Román et al. 2016). Two main assumptions appear to be important in this matter: first, a direct relationship between the chronology at the base of the archaeological sites and their location on marine landforms, and second, the marine hunter-gatherer settlements occurred immediately along the coastlines in all settings and progressively with the marine regression during the Holocene. Regarding the first premise, it is important to consider that the ages for the formations of the marine landforms can provide maximum ages for the archaeological record located above them, but not minimum ages. This fact is clearly illustrated, among other examples, by the long archaeological sequence at the Túnel I site (Fig. 8), situated in the Beagle Channel, which clearly shows that the shell midden formation took place at the same location from the Middle to the Late Holocene (Orquera and Piana 1999). The lack of direct association between the age of an archaeological site and the age of the marine landform where it is located was widely recognized by archaeologists

Shell Middens and Coastal Archaeology in Southern South America, Fig. 7 Excavation of shell midden in the Offing Island, western sector of the Strait of Magellan. (Photo: Manuel San Román; San Román et al. 2016)

Shell Middens and Coastal Archaeology in Southern South America, Fig. 8 Archaeological sequence of the Túnel I site (Beagle Channel): several episodes of shell deposition superimposed one on the other in the same place over 6000 years. (Photo: Luis A. Orquera)

in southern South America (Orquera 1984–85; Favier Dubois and Borella 2007; Reyes et al. 2017) Concerning the second assumption, the relation between occupation patterns in coastal settings by marine hunter-gatherers and the coastline evolution does not seem to be apparent in other areas of the Western Patagonian Channels. In the Beagle Channel, there was no correlation between the locations of sites above sea level and their chronology (Barceló et al. 2002). This regional difference between two adjacent archaeological landscapes creates interesting questions concerning how geological and environmental factors can affect the visibility of shell mounds

Shell Middens and Coastal Archaeology in Southern South America, Fig. 9 Shell midden section of the Imiwaia I: shell mounds around a central pit with occupations comprising chronologies from 6400 to 1500 BP. (Photo: Ernesto L. Piana)

and how in turn it influences the cultural interpretations about marine hunter-gatherers.

Fishing, gathering, and hunting activities determine the locations of settlements and the formation and spatial distribution of shell middens in an archaeological scale. Since changes in coastal configuration along the Holocene lead to variations in the distributions of exploitable resources, paleogeographical reconstructions enable a better understanding of the archaeological materials contained in shell middens. An interdisciplinary approach performed at Bajo de la Quinta (San Matías Gulf, Northern Patagonia) allowed the reconstruction of coastal landscape evolution and natural scenarios that could affect human decision-making on the use of the coast and its resources over time (Favier-Dubois and Kokot 2011). The spatial distribution of the archaeological evidence in simulated paleogeographic scenarios suggests that there were changes in fishing practices correlated to changes in coastal configuration through time (Favier-Dubois and Kokot 2011; Favier Dubois and Scartascini 2012). By comparing data from paleogeography and archaeoichthyology, Zangrando et al. (2016) have also been able to evaluate how changes in Holocene coastal geomorphology near the Imiwaia I site (Beagle Channel) influenced hunter-gatherer subsistence (Fig. 9). These results show that the abundance and taxonomic diversity recorded in ichthyofaunal assemblages at Imiwaia I coincide with the environmental expectations arising from paleogeographic reconstructions of the Cambaceres Bay during the Middle and Late Holocene.

Shell Middens as Niche Construction

Shell middens are very conspicuous accumulated forms in the coastal landscapes of the Beagle Channel. In the Cambaceres area, along a coastline of approximately 13 km and surrounding emplacements, Bjerck et al. (2016) have reported

more than 1200 structures. Archaeological surveys have also shown that more than 90% of the shell middens are located within 300 m of the coastline (Barceló et al. 2002). Although different shell midden types were recorded in that region (Orquera and Piana 1989–1990), the ring-shaped mounds are the most frequent feature, with a tendency to be clustered in large sites (Piana and Orquera 2010; Bjerck et al. 2016).

Excavations conducted in the Beagle Channel over 40 years indicate that the formation of shell middens resulted from repeated occupations at the same place. These reoccupations are indicated both by short-term but continuous accumulation rates of shells and by the reuse of the same places after long-term hiatus. This constant pattern in the archaeological landscape of the Beagle Channel leads archaeologists to assign a special role to shell midden formation, determining later use of space for human settlements (Piana and Orquera 2010). No evidence of seasonal-based bias in site formations was recorded (Estévez and Vila 2006). Ethnographic sources indicate that huts were located in these depressed sectors, and when people move to other place, those housing structures were neither turned down nor damaged. The abandoned hut could be later used by new occupants (Piana and Orquera 2010). Actualistic research, by the building of huts with similar shape, size, and constructive patterns to those observed in the ethnographical sources, shows that branched structures can last during several years (Piana and Orquera 2010). Ethnographic information also suggests that residential movements occurred frequently in a short time span, and lack of variation in the dimensions of the shell mound pits along the archaeological sequence does not allow us to assume significant variations in human mobility patterns in the last 6000 years (Orquera and Piana 1999). Central pits in shell mounds normally have diameters between 3 and 4 m (Barceló et al. 2002).

Initial settlement can occur as a consequence of multiple factors, such as a need for shelter, proximity to shell beds, access to water supply, etc. But once the first shell disposal happens, a repeated deposition of shells in the same location takes place, motivated by social and practical reasons. This pattern implies adding new volume of shell material to the mounds, increasing the depth of the pit leading to constraints in drainage because of rain and snowmelt. When a shell mound reaches an impractical size, a new adjacent hut may be raised, having part of the previous mound act as basal protection from wind and rain. Thus, new accumulations of shell mounds could have taken place around the new structure, progressively producing an agglomeration of ring-shaped mounds (Piana and Orquera 2010; Fig. 10).

The reuse of shell middens is also related to other visibility factors. Shell accumulations produce a high concentration of $CaCO_3$ in soils, modifying the environmental conditions for ground vegetation. Actually, vegetative covers of shell middens are colonized by particular species of grasses with distinctive green tones, which can be identified from long distances (Piana and Orquera 2010). This particularity was noted by Charles Darwin when he travelled areas bordering the Beagle Channel. In his travel diary he wrote (Darwin 1839: 234): "The inhabitants, living chiefly upon shell-fish, are obliged constantly to change their place of residence; but they return at intervals to the same spots, as is evident from the pile of old shells, which must often amount to some tons in weight. These heaps can be distinguished at long distance by the bright green colour of certain plants which invariably grow on them."

A Final Reflection: Shell Mounds, Visibility, and Potential Biases

The above discussion indicates that shell middens and shell mounds are cumulative structures, the product over years to centuries of multiple episodes of shell and cultural material deposition superimposed in the same location. Multiple occupations at the same spot are promoted by the visibility of these deposits, which could have resulted from conscious or unconscious factors. Therefore, shell middens archaeologically result in complex structures with a variable sequence of use and significance. This attribute leads to

Shell Middens and Coastal Archaeology in Southern South America, Fig. 10 Panoramic view of an agglomeration of shell mounds at the Cambaceres Bay (Beagle Channel). (Photo: Atilio Francisco Zangrando)

consider the shell middens as very high resolution deposits to the point of being able to define a certain number of occupations along an archaeological sequence (Estévez and Vila 2006). However, a paradox appears on this matter since it is quite possible that multiple occupations at the same spot produce a partial removal of successive deposits and a mixing of the different episodes of deposition (Bailey 2007, 2009). This assumption makes it difficult to divide the shell mound structures into their individual constituent episodes, but it is possible to identify patterns in overall site structure and trajectories through time, which can be interpreted in the light of additional information on variable patterns of site use and dwelling (Bailey and Galanidou 2009). Not ignoring the time-averaged nature of shell mounds, elaborate excavation techniques (Orquera and Piana 1992) and geoarchaeological studies (Villagran et al. 2010) have shown compelling results for understanding the formation processes of the mounds and their implications on social and subsistence practices of humans.

Shell middens are visible deposits of the past; they naturally attract archaeologists as locations with prehistoric coastal occupations and because of their good preservational context in comparison to other types of archaeological records. Shell middens are normally assumed as major archaeological indicators of human marine-orientated economies, and the occurrence and distribution of these deposits are evoked as an increase in the intensity of exploitation of marine resources. However, these assumptions can produce some biases in our understanding of those societies. Considering that shell mound formation represents a complex process where geological, ecological, and cultural factors interact (Reyes et al. 2017), one important precondition for the occurrence and visibility of shell middens is the local availability of shellfish and the persistence of the mollusc supply concurrent with changes in sea level and shoreline ecology (Bailey 2009). Thus, the lack of availability of shellfish restricts both the visibility and the good preservational context in the coastal archaeological record. In conclusion, it is not possible to

assume that the absence of shell middens is not in itself evidence for absence of littoral settlements along shorelines or the development of human marine-orientated economies (Bailey 2009). This simple observation, though rarely considered, has important implications for coastal archaeological research, especially to those concerning the first adaptations of native peoples to marine environments where shell gathering is not necessarily assumed as the primary human practice.

Shell Middens in North America

Katharine Vickers Kirakosian
Department of Anthropology, University of Massachusetts Amherst, Amherst, MA, USA

Introduction

Sites classified as shell middens have been identified by archaeologists on every inhabited continent and in every coastal area throughout the world since the mid-nineteenth century (Claassen 1998). Considering the high calcium content of shellfish remains, shell middens often contain amazingly preserved organic materials such as bone and textiles. They often have incredibly complex stratigraphic sequences as well, which helps to understand their usage over time. Given their high visibility and the fact that they are often threatened by erosion and development, shell midden sites are currently being destroyed at increasing rates.

Since shellfish beds (and essentially shell middens) are reliant upon stabilized sea levels, most shell midden sites date between 10,000 and 300 years ago. However, the frequency of shell midden sites throughout the world varies widely and is often connected to the presence of hunter-gatherer groups within a given region (Allen 2017) here. For example, the presence of shell middens in Europe often wanes during the Mesolithic/Neolithic transition (Milner 2002), while Native American groups were still reliant upon shellfish resources up until and even during the Contact Period on both the East Coast (i.e., seventeenth and eighteenth centuries) and the West Coast (i.e., eighteenth and nineteenth centuries). Notable exceptions include historic sites left from various local shell button industries (e.g., in Muscatine, IA; Leavenworth, IN; and St. Mary's, WV) (see, for example, Claassen 1994).

Definition

The term "shell midden" is a well-established site type in North America used to describe archaeological sites that contain large and dense deposits of freshwater and/or marine shellfish that were transported and/or somehow used by site inhabitants. Shell midden archaeology focuses on the use and significance of these sites through time and how they shed light on past human behavior and lifeways. "Shell mound," "kitchen midden," and "shell heap" have been used by archaeologists through time when discussing dense shell-bearing sites. Shell mound is still a commonly used phrase in the international archaeology community. Shell midden is the most commonly used term, while shell mound is a regionally preferred term throughout North and South America and tends to signify shell-bearing sites with great depth and a certain moundedness (Thompson et al. 2016). To be clear, while the same site type, "shell midden," is used across the globe, these sites are quite regionally diverse and did not necessarily serve the same function across cultures.

Historical Background

The genesis of American shell midden archaeology is largely dependent on early archaeological work across the Atlantic. The first large-scale investigation into dense shell sites of human origin was conducted in Denmark in the 1840s. Here the Royal Academy of Copenhagen established a three-man committee, which included Dr. Forchhammer (a geologist), Dr. Steenstrup (a zoologist), and Dr. Worsaae (an archaeologist), to investigate the dense shell sites on the Danish coast. Through their work, they accomplished two main things (Steenstrup et al. 2002 [1851]). First, they coined the site type "*kjoekkenmoedding,*" which translates to mean kitchen midden (later called shell heaps or shell middens in English). Secondly, they proved through excavations that these sites were created by humans and were not natural formations, as many previously believed.

It was not for a full decade after these early reports were published in Danish that Adolphe

Morlot translated their work into English (Morlot 1861). According to his reading of Forschhammer, Steenstrup, and Worsaae's reports, Danish *kjoekkenmoeddinger* had the following fifteen defining traits: (1) they were Stone-Age/hunter-gatherer sites, (2) they contained food refuse; (3) they showed evidence for long-term deposition, (4) they varied in 3-dimensional size and shape, (5) they were very close or within 2-miles of the shore, (6) they showed no evidence for stratification, (7) they had a predominately shell matrix, (8) they were part of or near a habitation, (9) they contained dense charcoal and ash deposits, (10) they had no floral remains, (11) they contained many shellfish species, (12) they contained many bird and mammal species, (13) they showed evidence that wild and/or domesticated dogs were eaten, (14) they showed evidence for seasonality, and (15) they did not contain human remains or burials (Morlot 1861). While some of these characteristics were likely assumptions based on the nascent nature of archaeology at the time (i.e., kjoekkenmoeddinger contained no floral remains), and while many of these characteristics are similar to shell midden sites throughout the world, some of these characteristics are not true of regional shell midden sites. In short, early-nineteenth-century research in Denmark established that *kjoekkenmoeddinger* (shell middens) were Stone Age sites that were the accumulation of shellfish food remains, an assumption that would not be contested until the late twentieth century.

Shell midden archaeology in America and beyond was highly influenced by these early Danish researchers, although regional shell midden sites are unique in terms of specific characteristics, form, and function. The next generation of late-nineteenth-century archaeologists inspired by the early Danish work included Dall (Aleutian Islands), Matthew (Canada), Morse (Japan), Putnam (Eastern United States), Rau (Eastern United States), Schumacher (Northwest Coast, United States), and Wyman (Northeastern and Southeastern United States) to name just a few. These researchers wanted to understand the complexities of these sites in a regional context and went into the field to identify and better understand local shell middens. Wyman was one of the first to conduct an in-depth investigation of shell middens in America (Wyman 1868). A trained doctor and the first curator at Harvard's Peabody Museum of Archaeology and Ethnology, Wyman traveled throughout coastal Maine and Massachusetts in the 1860s, accompanied by former students Frederick Ward Putnam and Edward S. Morse, to identify shell middens and to collect specimens for the Peabody's growing collection. Wyman was well versed in the earlier Danish work as well as Morlot's translations and was clear that these sites "yield nothing which indicates as high an antiquity as those of the old world" (Wyman 1868: 571).

One early debate that took hold in shell midden archaeology during the late nineteenth century related to the fact that many shell middens in the United States, for example, contained human remains. This information led early researchers to claim that widespread cannibalism existed among these groups. Researchers argued that if shell middens were places for food refuse disposal, then the presence of human remains signified the consumption of human flesh as well. In many instances, this spawned from and fed into assumptions at the time regarding Native people as "savage." In hindsight, many of these human remains were likely intentional human burials (both primary and secondary). Shell middens also provided evidence to some researchers that Native peoples in American had "uncivilized" taste leading up to European contact. For example, upon researching shell middens in Maine and Massachusetts (USA), Jeffries Wyman explained "Although the kinds of meat used were in the main palatable, the natives certainly did not hesitate to make use of some which did not commend themselves to the taste of civilized people" (Wyman 1868: 575). Not only did Native groups engage in cannibalism throughout the continent, but also their eating habits were uncivilized. The language in many early publications (and even today) describes shell midden sites as dirty, disorganized locales where people came, quite literally, to *throw* their trash. This is an assumption that becomes increasingly problematic when shell

midden sites contain intentional human burials, dog burials, and other potentially sacred spaces.

Key Issues/Current Debates

Shell midden formation processes: Shell midden sites are perhaps some of the most stratigraphically complex sites excavated by archaeologists (Stein 1992). One of the most thorough case studies on this point is the British Camp, which was a shell midden site that was occupied for at least two millennia on what is now San Juan Island, Washington. Here Stein and her crew excavated hundreds of facies (layers), which were identified depending on varying percentages of carbonate and artifactual data (Stein 1992). The British Camp showed that weathering and ground water movement, rather than simply cultural activity, can affect many layers at archaeological sites.

While it is clear that shell midden sites are stratigraphically complex sites, the term "shell midden" implies a certain similarity of form and function, as already discussed (Roksandic et al. 2014). Taking a rather theoretical approach, Bailey (2007) has referred to shell middens as "cumulative palimpsests" where "the successive episodes of deposition, or layers of activity, remain superimposed one upon the other without loss of evidence, but are so re-worked and mixed together that it is difficult or impossible to separate them out into their original constituents" (Bailey 2007: 204). In response to this, Moore (2015) has looked closely at the Green River sites in the southeastern United States and to break down the multitude of activities that occurred at these sites over generations into isolated events (i.e., burying a loved one, eating a meal, etc.). In essence, Moore takes a dwelling versus a building perspective. In the former, people dwell "in an ever-evolving lifeworld," while in the latter, people must first build a world before they can move in it (Moore 2015: 65–66). This perspective relates to site formation practices, although it is decidedly more agent-based.

Shell midden function: Historically, shell middens have been interpreted as places for food refuse disposal. Debates around the usefulness of the vague and all-encompassing site type "shell midden" began in the late 1980s with Widmer (1989), who urged that archaeologists should classify these sites in a way that did not *assume* site functionality (i.e., food refuse disposal). Widmer (1989) suggested differentiating between shell middens sites, shell middens, shell-bearing midden sites, and shell-bearing habitation sites, although few archaeologists classify their sites according to these criteria. Also, more neutral and all-encompassing terms like "shell-bearing site" or "shell matrix site" have been suggested, although the term "shell midden" has been hard to remove from the general archaeological lexicon (Claassen 1998).

In Claassen's (1991) chapter on "Normative Thinking and Shell-Bearing Sites," she strengthens Widmer's (1989) conclusion that we should refer to archaeological sites bearing shell as shell-bearing sites because "to use a more specific label would require the investigator to assess formation processes" (Claassen 1991: 252). Claassen (1991: 283) is quite clear that "Far too often in shell 'midden' research, basic correlations between human behavior and shell or site formation are assumed when they should be hypothesized." As a result, archaeologists may have "a false sense of knowledge upon which successive interpretations are built" (Claassen 1991: 284).

More recently Marquardt (2010: 551) reviewed the many proposed functions of shell mounds in the southeastern United States (also referred to as shell middens, shell heaps, shell rings, and shell works), which include "feasting, monumentality, burial ceremonialism, and identity signaling." Marquardt questions the boundaries between all of the terminology surrounding dense shell sites, asking "But when do shell mounds qualify as monuments? As ceremonial sites? As temple mounds? As indicative of feasting behavior? What makes a shell mound a 'shell work' or a 'shell ring'? I argue that much depends on the initial assumptions of the analyst and on her or his calculus of verification" (Marquardt 2010: 554). This piece brings up important issues with archaeological terminology as correlated with site form and function, which

are not yet resolved (Claassen 2010). Marquardt's work correlates with the author's dissertation research in Massachusetts, where several professional archaeologists admitted that although hundreds of shell midden sites were listed in the state's site files, "real" shell middens did not exist in the area (see Kirakosian 2014). There are clearly regional struggles with the application of this terminology, especially when archaeologists so steadily recognize it globally.

Shell middens and local chronologies: Before the advent of radiocarbon dating, shell middens were vital in establishing regional master chronologies and stone tool and pottery typologies, given their stratigraphic complexities and high artifact content. Research into these areas took hold in the culture-historic period in archaeology although this research has continued until the present day (see, for example, Rick et al. 2014; Pluckhahn and Thompson (2017)). Indeed, shell middens aided Worsaae when he created his first basic chronology and were also hugely important to the establishment of early chronologies and stone tool typologies of southern California and Massachusetts (Gallegos 1987; Kirakosian 2014).

Sampling shell midden sites: Shells from shell middens were not routinely collected at all from shell midden sites until well within the twentieth century (Claassen 1998). In many regions, only shells made into tools were collected from shell midden excavations until well into the twentieth century. Collecting shellfish from shell midden sites became much more common place after field methods became more rigorous and strategic. Since shell middens contain such large quantities of shell, researchers have often struggled with how to sample these sites and collect representative samples without collecting tons of shell per site. Sampling shell midden sites becomes increasingly complicated because oftentimes shell middens are so large, that site boundaries are not full established. Field strategies to adequately sample shell midden sites have ranged from trenching, augering, coring, and collecting flotation samples, although approaches vary regionally as well (Claassen 1998; Stein 1992; Waselkov 1987).

Quantifying shell middens: In the United States, quantifying shellfish remains by weight has been a common practice since its genesis by E.W. Gifford and the California School of Midden Analysis during World War I (Mason et al. 1998). Many have used weight to infer the amount of shell meat brought to a site, although this approach fails to account for the effects of taphonomy. Another chronic problem with using shell weights occurs when a small number of samples are used to make generalizations about a site, with the assumption that shell middens are homogeneous. Weights also mask the fact that some species have very heavy shells and little meat and vice versa. MNI is also more reliable in terms of estimating species abundances and it is faster than weighing; calculating weight requires one to separate all of the fragments into groups by species, which can be very difficult with heavily fragmented shell, while calculating MNI only requires separating out the non-repetitive elements by species and counting those. Finally, MNI is a better method for statistical analysis because it is a "discrete, interval-scale level measurement" (Mason et al. 1998: 309). With this in mind, weights are not as useful when looking at questions of population dynamics and overexploitation (Mason et al. 1998). Weight is the most reliable, according to Glassow (2000: 413), for highly fragmented shell assemblages, while using MNI would be more appropriate with largely fragmented shells or if the shell quantities are not high per excavation unit. Such choices would also certainly depend on the species involved, the preservation, the screen-size used, and/or the number of flotation samples taken at the site. Weight can be less reliable than MNI because it is affected by so many other variables, such as site preservation, screen size, shell weight and age by taxa, shell fragmentation. However, one could argue that many of these variables also affect MNI. In many cases, using MNI is more reliable, while using weight can lead to false interpretations (Mason et al. 1998). Calculating both weight and MNI may be the best approach, although both can be affected by methodological choices like screen-size.

Dietary reconstructions: Shell middens provide interesting information about ancient diet. Shell midden data often reflect ancient population's reliance on shellfish. However, the reverse can also be true. For example, stable isotope analyses on the human remains buried at the Turner Farm site in Maine showed that "the site's Susquehanna tradition occupants, surrounded by the riches of the sea, apparently made little use of them, consuming less marine protein than any other coastal population known to us" (Bourque 2007: 2). It is also important to point out that because shell preserves quite well and shell middens are quite large, this may lead to certain biases in terms of archaeological interpretations on the importance of shellfish resources to ancient peoples. With this in mind, it is also true that shellfish are also collected for purposes other than direct human consumption, such as bait (Claassen 1998).

Interestingly, early research here focused on Optimal Foraging Theory, which may have biased archaeological understandings reconstructions of shellfish consumption. Assumptions about efficiency and effort are called into question when ethnographic accounts are taken into consideration (i.e., Meehan 1982). In some early studies, in order to estimate rough population size that could have been sustained by a particular midden, the number of calories was calculated based on the number of shells present and the time in which the midden was formed. These estimates relied on many assumptions, of course, and are not generally standard practice today.

The dietary implications of isotope analysis are intriguing, although due to concerns over the treatment of Native American human remains, few studies of this kind have occurred in the United States over the past few decades. Some early carbon and nitrogen isotope research that relied in part on shell midden data from Nantucket, MA, led Little and Schoeninger (1995: 364) to conclude that the Late Woodland period diet of indigenous Nantucketers was reliant on marine foods much more so than "the dominance of mammal bone in the archaeological shell middens indicates." Interestingly, these isotope data show a heavier reliance on fish, although few fish bones show up in local shell middens. In short, Little and Schoeninger (1995: 351) believe that the Late Woodland Nantucket diet was "40–65 percent oceanic animals, with the rest consisting of substantial amounts of animals from salt marsh and eelgrass meadows or of maize, and minor amounts of C3 plants and their consumers." As their data were inconclusive in terms of the importance of maize within the diet, the authors called for more research to decipher the difference between maize and salt marsh and seagrass meadow resources, which have a similar signature.

Trade and craft specialization: Shell middens sites also show evidence for larger trade networks and regional craft specialization. A reconnaissance survey by Mitchell and Foster (2000) on outlying prehistoric Hohokam shell middens in Sonora, Mexico, offered evidence that the Hohokam and other local groups were going into modern-day Mexico for over a millennium to gather raw shell for ornament production. The Hohokam are known for their shell craftsmanship, which moved extensively throughout the southwest regional trade. These shell middens also show evidence that some shellfish species were collected for food as well, based on the breakage patterns of many species.

In New York, the mid-seventeenth-century Fort Massapeag is believed to be a locale of wampum manufacture during the height of the Fur Trade (Cantwell and Wall 2003). A shell midden found just outside the fort's palisade walls contained shells in all stages of wampum manufacture as well as tools associated with wampum production. Researchers have estimated that this site was "a place where the Passapequas, probably those living in the nearby village, gathered to make the money that joined their economy with those of Europeans and Iroquoian peoples in the interior" (Cantwell and Wall 2003: 138). This site shows yet another complex and unique story behind an American shell midden site.

Shell middens as socially significant spaces: As already suggested, shell midden sites offer many clues about past lifeways beyond dietary choices and environmental variability. One shell midden in particular that has been the subject of

discussions surrounding gender and social status differentiation in the past is the Indian Knoll Site. Located on the Green River in Kentucky, this shell midden site contained hundreds of burials dating to the Archaic period and contained tens of thousands of artifacts, including copper and marine shell artifacts. The inclusion of these artifacts among burials, including male, female, and children's burials, shows that such prestigious objects were not solely possessed by any one age group or gender (Jefferies 1996). Analyses of human remains from this site also show relatively little difference between the health of the larger population, implying that those interred in the Indian Knoll site lived in a largely egalitarian society with some social differentiation based on a complex array of individual factors (Jefferies 1996).

While shell midden sites like Indian Knoll have illuminated the ancient past, they can also shed light on the more recent history of archaeological science and the paradigmatic shifts and times of the archaeologists working on such sites. For example, starting in the 1980s, archaeologists began to reconsider the conclusions of earlier researchers on sites like Indian Knoll. When initially excavated in the 1930s as part of the WPA program, William Webb (and later Howard Winters) connected certain artifact types to activities that both men assumed were decidedly male or female in nature (i.e., food-processing as female activities while trade and hunting were solely male spheres). In particular, Winters found the inclusion of atlatl weights in women's graves particularly difficult to explain. In their seminal paper, *Archaeology and the Study of Gender*, Conkey and Spector (1984: 11) explain that comparing the archaeological evidence at such sites to the archaeological interpretations can show "how preconceived notions about gender arrangements can confuse, in fact contort, archaeological interpretations."

In the Northwest Coast, Moss (1993) has shown how shellfish, gender, and status were inextricably linked in complex ways. Using archaeological, ethnographic, and ethnohistoric data, she examines the ways in which shellfish had dietary, economic, social, and symbolic importance among the Tlingit. Here women consumed shellfish in larger quantities than men, although women's consumption of shellfish was highly regulated at certain times (i.e., during menstruation). This may be complicated, however, by the fact that shellfish were seen in historic times, as "less desirable" foods, making consumption somewhat taboo to openly discuss and therefore underreported. This is important to take into consideration as well, when comparing ethnographic and ethnohistoric data to archaeological data in the region, which shows an increase in the presence of shell midden sites after 5500 B.P. (Moss 1993). In short, scant "ethnographic data on shellfish may be partly responsible for some archaeologists regarding shellfish as inconsequential resources" (Moss 1993: 631).

Symbolic significance of shell: Regions with many shell midden sites with unique contents and configurations, like the Green River in Kentucky, have led researchers over the past few decades to closely consider the symbolic significance of shell in various regions throughout the United States. For example, Claassen hypothesizes that the Green River shell middens might have been restricted to the Archaic period (AKA Shell Mound Archaic) because of human agency – namely women's choices. According to her theory, women did not just collect shellfish for economic purposes, but because "of its prestige value, because it provides social enjoyment, because it fits with child rearing, or because it allows one to realize spiritual goals" (Bruhns and Stothert 1999: 72). The Shell Mound Archaic, according to Claassen, was connected to the economic and religious significance of shellfish and its association with fertility. As a result, the collecting and mounding of shell on this level ceased with the introduction of plant domesticates. In this vein, "Claassen postulates that the old religious metaphors were mooted by new ideas associated with the cycle of planting, growing, and harvesting, and that the gourd replaced the shell as the most provocative fertility symbol" (Bruhns and Stothert 1999: 73). Shell middens in this region were still important as residential and ritual locales, although many were capped by soil versus shells, which were subsequently discarded elsewhere.

Working in the Northeastern United States, Kerber (2002) also contends "shellfish could have been collected for both consumption of the meat and ideology of the shell" (Kerber 2002: 24). In this and other regions throughout American, he is also "curious of the myriad reasons why burials were put within deposits also containing shellfish remains, and, conversely, why shells individually and/or collectively were placed in burials" (Kerber 2002: 27). Until rather recently however, shellfish remains were almost always directly and unquestionably linked to dietary practices.

International Perspectives

Varied promising research on shell middens has occurred outside of the United States. While it is impossible to highlight even a small fraction of the important work that has been done to further shell midden research throughout the world, the work of a few key researchers and organizations is highlighted. For example, Meehan (1982) completed one of the first ethnoarchaeological projects, in which she documented shellfishing practices among the aboriginal Anbarra women in Australia. Her work was highly influential and has shed light on the diverse lived experiences surrounding shellfishing that might have been otherwise overlooked by archaeologists.

The work of British archaeologist Geoff Bailey is also quite noteworthy, as his work spans shell midden research throughout Europe, Australia, the Near East, and Africa. One of his more recent projects has involved stable isotope research on human bones dating from the Mesolithic and Neolithic to better understand dietary shifts between these two time periods. His work on the Weipa shell mounds in New Zealand has been quite interdisciplinary and far-reaching and has included surveying and excavating shell mounds, tracing the changing shoreline of the region, dating shell mounds, looking at palaeoenvironmental and palaeoclimatic data, as well as recording the oral histories of the Napranum community, who are the traditional Owners of this region. Also, as the Principal Investigator of the Dynamic Landscapes, Coastal Environments & Human Dispersals (DISPERSE) project, Bailey has also collaborated on ground-breaking shell midden explorations on the Farasan Islands in the Red Sea, which involved underwater archaeology and remote-sensing to map palaeoshorelines (Hausmann et al. 2015). Since so little is known about these shell middens, fieldwork here has been highly exploratory since 2006. Bailey also organized a fruitful conference at the University of York in 2005, which resulted in another important book on the topic of shell middens in Europe (Milner et al. 2007). Another fruitful meeting, organized by Bailey and Karen Hardy, focused on "Shell Energy" and was held in Dakar, Senegal, in 2008 and resulted in an edited volume of the same name (Bailey et al. 2013). In 2011, Bailey was also part of a team that tested a new method of amino acid racemization (AAR), which has far-reaching implications for shell midden research throughout the world (Demarchi et al. 2011). In short, Bailey's work touches upon many diverse specialties that have far-reaching implications for shell midden researcher across the world.

The Archaeomalacological Working Group (AMWG) of the International Council for Archaeozoology (ICAZ) is an important group that focuses in part on shell midden research. Looking back at the topics of their meetings since 2005 also gives a sense of shifting research trends over the past decade:

- 2005: The Status of Archaeomalacology in the twenty-first Century (Gainesville, Florida)
- 2006: Shells of Mollusca: Environmental Adaptations, Ideological Expressions (Mexico City, Mexico)
- 2008: Not only food (Santander, Spain)
- 2010: Archaeomalacology: Shells in the Archaeological Record (Paris, France)
- 2012: Advancing Method, Enhancing Understanding: Technique and Narrative in Archaeomalacology (Cairns, Australia)
- 2014: Global Patterns in the Exploitation of Animal-Based Raw Materials: Technological and Socio-Cultural Issues (San Rafael, Argentina)
- 2016: Methods in our Madness: Approaches to Archaeomalacology (Kirkwall, Orkney Island)

Future Directions

Shell midden archaeology has seen many developments over the past century. The future of this specialty will likely involve collaborations with researchers outside of archaeology around increasingly complex, yet relevant research questions. For example, there is much work yet to be done on shell middens and paleoenvironmental reconstructions and how these can inform climate change science. Shell midden analysis can also help biologists understand species diversity and habitat loss through time. Research into shell beyond diet also has great potential, including the spiritual significance of shell within shell midden sites throughout the world. Ethnographic research into shell collecting and shell midden formation processes, similar to Meehan's early work, could help with many unanswered questions surrounding these topics. In short, archaeologists studying shell middens must form interdisciplinary teams to better understand these complex sites and their varied significance in the past as well as in the twenty-first century.

Shell Middens of the Arabian Sea

Paolo Biagi
Department of Asian and North African Studies, Ca' Foscari University of Venice, Venezia, Italy

Introduction

In 1848, the Danish Academy of Sciences and Letters promoted the formation of a commission whose scope was to study a phenomenon well-known along the northern coasts of Denmark. The main purpose of the commission, originally called Lejra Commission, was to verify whether the presence of oyster heaps along the coast of Jutland was due to natural causes or to some kind of human activity, as the presence of archaeological implements on the surface of Krabbesholm would suggest (Andersen 2000). The discovery of an impressive shell midden at Meilgård, in the Jutland Peninsula, where the commission, composed by J.J.A. Worsaae, J.J.S. Steenstrup, and J.G. Forchhammer, collected knapped stone tools and animal bones, showed for the first time that the shell mounds were undoubtedly prehistoric sites and not simply natural formations due to the ocean's waves and that the heaps of shells were just accumulations of food refuses (Kristiansen 2002).

The excavations carried out a few years later by J.J.A. Worsaae demonstrated for the first time that the impressive shell mound of Meilgård was a prehistoric site and not a sequence of naturally deposited over-imposed layers of marine shells and sterile horizons. Moreover, the site was undoubtedly to be attributed to a period preceding the Neolithic on the basis of the lithic finds and

wild animal bones. This type of sites was called *Køkkenmødding* (shell midden) a term later systematically employed in the archaeological literature (Szabó 2017). Following this discovery, the first excavation of one of the most important shell middens of Denmark, Ertebølle, was carried around the end of the 1800s (Fischer and Kristiansen 2002). At present we know that the shell middens of Denmark are to be attributed to different periods of prehistory and that their presence is probably due to the variable saline content of the ocean and consequently to the possibility of exploiting different marine resources.

Definition

As mentioned above, shell middens greatly contributed to the study of the early development of archaeology in Denmark and other Scandinavian countries in particular (Gräslund 1987). They are well-known from many countries around the world, among which are those along the coasts of the Arabian Sea. Though they have simply been defined as "refuse deposits in which molluscan shell is one of the major constituent materials" (Szabó 2017: 772), they consist of important archaeological archives, rich of different types of organic material, whose study can provide us with much information regarding the diet followed by their inhabitants, seasonality of occupation, characteristics of the landscape around the sites and its logistic use, as well as changes that affected the local environment due to either natural events or human interference. The study of shell middens tells us the way coastlines changed through time, how and when people moved or migrated, and the periods when marine, mangrove, and riverine ecosystems were exploited (Codding et al. 2014) by mobile or more sedentary fisher-gatherers. Moreover, shell middens can be radiocarbon dated because of the presence of a great variety of food refuses, mainly marine or mangrove or freshwater mollusks, as well as charcoal and other organogenic remains, among which are fish, turtle, and mammal bones.

Shell middens are often distributed in areas of so-called ecological tension, that is, areas very favorable to the exploitation of different environments, where all the resources necessary to the subsistence of their inhabitants were available. Though many shell sites are composed mostly of food refuses, nevertheless some show that other activities were practiced, among which is the production of ornaments and other specific items, among which are lime and bite for fishing or for preservation and later consumption (Szabó 2017: 779–780). They have been classified into four categories, according to their main characteristics: composition, function, exclusive recurrence of shellfish, and presence or not of habitations, burial grounds, and other types of consistent or ephemeral structures, among which are hearths and fireplaces (Claasen 1991: 252) that might help improve our knowledge regarding activities practiced at the sites and their eventual ethnoarchaeological interpretation (Hardy et al. 2016).

Historical Background

The shell middens described and discussed in this paper were discovered or excavated along the western and northern coasts of the Arabian Sea and the Gulf of Oman (Fig. 1). A few more were excavated in the Gulf of Aden by the Russian archaeological expedition in Yemen (Amirkhanov 2006: 534–583). The impressive urban development that took place in this part of the Arabian Peninsula during the last 50 years led to an intensification of both rescue and research archaeological excavations and surveys that were promoted mainly by the governments of the United Arab Emirates (UAE) and the Sultanate of Oman. In contrast archaeological research was not very productive along the northern coast of the Arabian Sea. This was due to political problems, among which are instability and insecurity, absence of interest by local authorities, universities' inactivity, and logistic difficulties. In effect, except for the geoarchaeological surveys carried out by Professor A.R. Khan of the Department of Geography, Karachi University in the late 1970s (Khan 1979), the French Archaeological Expedition in Makrani Balochistan (Sanlaville et al. 1991), and the Italian Archaeological Expedition

Shell Middens of the Arabian Sea,

(Drawing by P. Biagi)

in Lower Sindh and Las Bela (Balochistan) and the Indus delta (Sindh) between 2007 and 2014, very little attention has ever been paid to the prehistoric archaeology of this very important coastal region (Biagi et al. 2016).

According to the chronicles of the classical authors, both the Arabian Sea coastlines discussed in this entry were settled by groups of fish-eaters (*ichthyophagoi*) at least during Hellenistic times and the first centuries AD. The two countries have similar landscapes and share comparable environmental conditions. Broadly speaking, these semiarid regions are rich in sandy or gravelly deposits whose bare, treeless surfaces in many cases have favored the discovery of prehistoric sites or isolated items. Moreover, both coastlines are affected by seasonal monsoon episodes, though with different intensity and precipitation rates (Snead 1969; Gupta 2004). In both regions, shell middens have been found close to the shore of ancient lagoons that began to dry up around the end of the Bronze Age and progressively disappear following the climate worsening that took place in that period, which led to the present arid conditions and contributed to the collapse of the Indus Civilization (Berger et al. 2013).

In the Sultanate of Oman, many shell aceramic middens have been discovered at the top of flat, rubified limestone terraces protruding toward the sea, often located close to the mouth of wadi courses. The available data show that around the beginning of the Holocene, the general climate of the region was more humid than that of the present. In this period many mangroves flourished along the shores of shallow lagoons, where watercourses flew into the Arabian Sea (Berger et al. 2005). This fact is confirmed also by the composition of the faunal and charcoal remains identified from the shell middens of both regions. Moreover, the recovery of fish hooks made from marine shell, double-pointed bone gorges, and net sinkers obtained from beach and wadi pebbles shows that in many cases (e.g., in the Sultanate of Oman), the subsistence economy of their inhabitants was based not only on the collection of marine and mangrove shells but mainly on fishing, the exploitation of mangal resources, and in some cases hunting and also the breeding of domestic animals (Woodman 2013).

One of the main problems to be faced in the study of Arabian Sea shell middens regards their chronology. It is well-known that the marine and mangrove shells yield different $\delta^{13}C$ (positive in the case of marine specimens and negative in the case of mangrove samples), and they both are problematic to calibrate according to the different areas from which the samples have been collected. These problems have already been discussed in many papers written by several authors who reached controversial results (see, for instance, Biagi 1994; Uerpmann and Uerpmann 2003; Biagi et al. 2012; Zazzo et al. 2012). In the case of the shell middens of Las Bela and Lower Sindh,

Shell Middens of the Arabian Sea, Fig. 2 The Cape of Ra's al-Hamrā with the location of sites RH-5 (yellow dot) and RH-10 (red dot) excavated by the Italian Archaeological Mission. (Helicopter photograph by R. Salm 1986)

their calibration has been obtained according to the data provided by a core drilled in the ocean, ca 300 km north of port Okha, with a regional mean of 229 ± 27 ^{14}C years. The calibrated dates have been compared with those obtained from charcoal retrieved from Chalcolithic (Amri culture) and Bronze Age sites (Indus Civilization) of the same region, with good results. However, the calibration of the Omani shell middens is still controversial because of the variety of locations, material and laboratories employed especially during the last 30 years, and the absence of a systematic program of dating.

Current Debates

The Western Coast of the Arabian Sea

The first shell middens of the Oman Peninsula were discovered in the 1970s on the cape of Ra's al-Hamrā (Red Cape) at Muscat (Durante and Tosi 1977) by R. Jäckli of Petroleum Development Oman (PDO). The headland protrudes toward the sea at the southern end of the Batinah coast (Fig. 2). It faces a unique, very productive marine ecosystem that still nowadays is intensively exploited in some seasons because of its richness (Biagi and Nisbet 1993). Most of the Ra's al-Hamrā shell middens lie at the top of this flat, rubified limestone terrace that elongates east of the mouth of Wadi Aday. Here the rich freshwater supply of the wadi course favored the formation of the Qur'm mangrove swamp, at present a national park (Uerpmann and Uerpmann 2003). In contrast, the oldest shell midden so far known discovered in the same area, RH-6, is located on a lower terrace, very close to the right bank of the same wadi (Fig. 3), just a few meters above the maximum high reached by the tide (Biagi 1999). Most of the Ra's al-Hamrā shell middens were destroyed before the end of the 1970s due to increasing building expansion. During those years, only a few Ra's al-Hamrā sites were partly excavated or test-trenched (RH-3, RH-4, RH-5, RH-6, RH-7, and RH-10), and just one was partly preserved for future research (RH-6).

Shell Middens of the Arabian Sea, Fig. 3 The mouth of Wadi Aday and the mangrove swamp of Qur'm with the location of site RH-6 (yellow dot). (Helicopter photograph by R. Salm 1986)

The radiocarbon dates obtained during many years of excavations carried out at Ra's al-Hamrā constitute the backbone of the chronology of the Holocene peopling of the northern coast of the Sultanate (Biagi 1994). During the mid-Holocene period, shell middens started to be settled and sometimes used also for other purposes, as graveyards, for example. The radiocarbon chronology of the Ra's al-Hamrā shell middens was developed almost exclusively from samples of marine and mangrove shells, as well as terrestrial and mangrove charcoals collected from the almost uninterrupted sequences of two neighboring shell middens: RH-6 and RH-5. All samples were processed at East Berlin (former DDR) radiocarbon laboratory headed by H. Quitta (Bln-). The results showed that the two sites were repeatedly (seasonally?) inhabited throughout a period of ca 1000 years each, roughly from the middle of the seventh to the second half of the fifth millennium BP, with a gap of a few centuries between the sequences of the two sites (RH-6, from 6530 ± 60 BP, Bln-3637/II to 5750 ± 60 BP, Bln-3636/I; RH-5, from 5395 ± 85 BP, Hv-10925 to 4730 ± 60 BP, Bln-3135). A few more dates were obtained also from sites RH-3, RH-4, and RH-10 (Biagi 1994).

The importance of fish in the diet of the RH-5 inhabitants has been interpreted thanks to the study of the bone remains, where fish represents ca 80% of the total assemblage (Fig. 4). According to their results, Uerpmann and Uerpmann (2003: 180) concluded that fishing of small species, among which are sardines, was one of the main strategies followed by the inhabitants of RH-5, though their marine subsistence economy relied mainly on larger fishes. This observation is suggested also by the presence of different types of shell fish hooks, bone gorges, and net sinkers made from stones (Uerpmann and Uerpmann 1996: 134).

At least four Omani shell middens yielded evidence of local shell fish hooks manufacture. At RH-6, fish hooks made from *Pinctada*

Shell Middens of the Arabian Sea, Fig. 4 Location of the site GAS-1 at Wadi Shab, near the white house along the terrace facing the Arabian Sea in the background. (Photograph by P. Biagi 1992)

radiata marine shells started to be produced locally during the first two centuries of the sixth millennium BP, according to a series of radiocarbon dates obtained from the archaeological layers where the shell hook workshop was uncovered (5980 ± 60 BP, Bln-3641/I and 5830 ± 80 BP, Bln-3640/I; Biagi 1999: 41). However, the radiocarbon evidence from other sites, namely, GAS-1 at Ash Shab (Fig. 5), Khor Milkh near Tiwi, and Ra's al-Khabbah (Cavulli and Scaruffi 2011), shows that shell hooks continued to be manufactured in a similar way throughout the entire fifth millennium BP. Net sinkers of oval or spherical cross section made from wadi or beach pebbles are characterized by pecked or sawn notches or one or two engraved lines. They have been found in large numbers from many middens of the Oman coast, together with other ground stone tools among which are different types of hammerstones, crushing stones, and anvils. The net sinkers vary in size, shape, type, weight, and technology of manufacture. Their variability might reflect different fishing techniques practiced at the sites according to the variability of marine environment and most probably also chronology.

Some of the Omani shell middens are multistratified (see RH-6 and RH-5 at Muscat, for instance). Their sequences consist of overimposed and intercalated layers and lenses of marine and mangrove shells (*Terebralia palustris*), fish, green turtle (*Chelonia mydas*), wild and domestic mammal bones, ash, charcoal, and wind-blown sand (Biagi and Nisbet 1999: 46). Many sites yielded evidence of different types of structures. The commonest consists of semicircular or circular dwelling features delimited by postholes or small C-shaped narrow canals, postholes, (rubbish) pits, hearths, and fireplaces (Biagi and Nisbet 2006).

Primary and secondary graves were also excavated from some of the middens. The most important prehistoric cemetery so far discovered is that of RH-5 (Fig. 5). It was excavated in the 1980s during six long seasons. The graveyard

Shell Middens of the Arabian Sea, Fig. 5 Tombs from the prehistoric graveyard excavated at RH-5 by S. Salvatori of the Italian Archaeological Mission. (Photograph by P. Biagi 1984)

extends over a surface of ca 160 sqm within a well-defined area of the settlement site. The cemetery was not in use throughout the entire life of the site (for its absolute chronology, see Biagi and Nisbet 2006: 226). It yielded the remains of 215 individuals, buried in three main different ways, most of whom passed away at 20–25 years of age. They were uncovered from 121 grave pits. Most bodies were found crouched on their left side within simple oval pits, with their hands placed in front or just under the face (Salvatori 2007; Zazzo et al. 2012). Secondary burials have also been recovered, as well as sparse bones of partly burnt skeletal remains sometimes in anatomical connection, scattered within a wide circular structure delimited by a line of stones. Arrowheads made of shark fishes were also recovered from this latter area. The grave goods consisted of simple, personal ornaments made from oceanic shells, among which are fish-like pendants, necklaces, and bracelets, as well as earrings, and a few beads, made from green steatite, and a few real pearls.

A long survey was carried out between 1983 and 1988 along the coast of Oman from Muscat, in the north, to Ra's Sharbitat, at the Dhofar border. It showed for the first time that shell middens are present also in other parts of the coastline, though their characteristics vary region by region as well as their chronology.

The first sites were discovered along the coasts of the bay of Bandar Khayran, a few kilometers east of Muscat, where 12 shell middens composed almost exclusively of heaps of marine bivalves (*Anadara uropigimelana*) were found and radiocarbon dated to different periods of the sixth millennium BP. Moving southward, the coastal strip between Dibab and Qalhāt revealed the presence of more shell middens. The shell midden of Dibab is located on a limestone terrace facing the ocean at the mouth of Wadi al-Araybiyin. This site was radiocarbon dated to the sixth millennium BP by a sample of marine shells. Similar dates were obtained from the important site of GAS-1 located on a high terrace facing the ocean at the mouth of Wadi Shab. The coastal strip that elongates between Sur and Ra's al-Hadd also yielded evidence of many sites, the highest number of which was discovered around the gulf of Khawr al-Jaramah. The remains of an important, though still undated village made of stone structures, were discovered close to Shiya (SHI-4east). Interestingly enough, the shell midden of Sur is located inside the walls of a Portuguese fort (Biagi 1988) (Fig. 6). Moving south of the cape of Ra's al-Hadd, other shell middens were discovered at Ra's al-Khabbah, Ra's Ruways, Ra's al-Sharik, Ra's Jibsh, Ra's Halat, Ra's Shirab, Ra's Hadid, and Suwayh, where the site SHW-11 was radiocarbon dated to the end of the eighth millennium

Shell Middens of the Arabian Sea, Fig. 6 The shell midden of Sur located inside the walls of the Portuguese fort. (Helicopter photograph by R. Salm 1986)

BP (Lézine et al. 2002; Berger et al. 2013). The surveys made between 1983 and 1988 showed the great archaeological potential the Omani coastal zone. They also showed that the Oman coast is rich in good-quality, knappable chert and jasper outcrops that were both exploited by prehistoric communities during different ages at least from the Neolithic to the Bronze Age.

Moreover, recent surveys promoted by the French Archaeological Mission in Oman, along the coasts of the Island of Masirah, led to the discovery of many prehistoric sites among which are shell middens, the most important of which are the Neolithic settlement of Ra's Dah, the oldest so far discovered in Oman, and the Early Bronze Age sites of Jebel Sfaiq and Marsis-A. According to the French colleagues, further investigations of these sites might shed light "...on the arrival of the famous 'black boats of Magan', loaded with products from far away 4500 years ago, as well as that of other, earlier boats, made of reeds or even logs. Eight thousand years ago, Neolithic populations would have easily crossed the 20 km that separated the island from the continent. This history of the first Neolithic peoples seeking new territories has yet to be written" (Charpentier et al. 2013: 12).

The Northern Coast of the Arabian Sea

The surveys, carried out by the Italian Archaeological Mission along the northern coast of the Arabian Sea in Las Bela province of southeastern Balochistan (Pakistan) between 2000 and 2014, led to the discovery of three main areas with evidence of palaeo-mangroves. They are located either close to the present coastline or a few kilometers inland, in the territory that extends between Miāni Hor (Sonmiāni Lagoon), in the north, and the Hab River mouth, in the south. Thanks to a systematic program of radiocarbon dating, 84 assays were obtained from specimens of *Terebralia palustris* and *Telescopium telescopium* mangrove gastropods and 22 more from seashells (*Purpura panama*, *Meretrix* sp.,

Ostreidae, *Lunella coronata*, *Turbo bruneus*, Mactridae). The radiocarbon dating program, still underway, provides us with a first detailed data set aimed to the reconstruction of the early exploitation of mangal resources that took place in the region between the mid-Holocene Atlantic period and the present (Biagi et al. 2016). According to the available data, mangrove swamps started to be exploited most probably during second half of the ninth millennium BP. This fact is suggested by one radiocarbon result obtained from a fragment of a bivalve seashell with a negative $\delta^{13}C$ of −4.44 that shows its mangrove provenance. The specimen was retrieved from the surface of a Mesolithic site discovered in the Kadeji River gorge (KDJ-1, GrA-63862, 8275 ± 45 BP), ca 40 kms north of Karachi, in Lower Sindh (Biagi 2018).

As reported above, the archaeological research still underway has been coupled with a program of systematic radiocarbon dating of mangrove (*T. palustris* and *T. telescopium*) and seashells. Its scope is to define the chronology and intensity of exploitation of the local mangal forests by prehistoric communities and to interpret the changes that took place in the coastal region that extends between Las Bela and the Indus delta throughout a period comprised between the beginning of the Holocene and the present. Moreover, it aims to study not only the typological characteristics of the material culture remains (knapped, ground stone tools, and ceramic potsherds, whenever they are present) but mainly to interpret the radiocarbon results obtained from one single adult specimen of mangrove gastropod (mainly *T. palustris* but also *T. telescopium*) weighing from ca 5 to 10 grams. The samples have dated at Groningen University isotope research laboratory (CIO): GrA- in the case of AMS dates from one individual and more specimens of the same species in the case of ordinary dates (GrN-) processed before 2004, when AMS facilities were not available.

Two main areas of the Las Bela province of southeastern Balochistan have been taken into consideration: (1) Lake Siranda, it consists of a saline depression, ca 15 km long and 3.5 km wide. Its southwestern side is situated ca 5 km from the northern shore of the Sonmiāni Lagoon (Miāni Hor) and ca 15 km from the present Arabian Sea coastline (Fig. 7). In January and August, the depression is sometimes filled by seasonal monsoon rains and, more rarely, by small freshwater streams flowing from the north (Biagi 2013). (2) The coast between Cape Gadani and the Hab River mouth that marks the boundary between Balochistan and Sindh, with its low, long sandy shores (see, e.g., the Bay of Daun) and a few headlands of solid, massive rocks (see, for instance, Ras Gadani, Ras Phuari, and Sonari north of Cape Monze at the boundary with Sindh) (Biagi et al. 2013).

Lake Siranda Palaeo-Lagoon

A detailed radiocarbon sequence showing the intensive, though most probably seasonal, exploitation of palaeo-mangroves is at present available from the so-called Lake Siranda depression located ca 20 km south of the small city of Uthal in the Las Bela plain. The early morphological history of the basin is still poorly known and even less understood (Snead 1969). It has been suggested that it was formerly part of the Sonmiāni Bay (Miāni Hor) and that it functioned as a tidal lagoon at least until the beginning of the dramatic events that led to the decline and fractionation of the Bronze Age Indus Civilization that took place around the end of the third and the beginning of the second millennium cal BC (Biagi et al. 2016). The radiocarbon dates so far obtained from the shell middens discovered along its shores show that the first exploitation of the local mangroves took place during the last two centuries of the eighth millennium BP and continued almost uninterruptedly throughout the entire seventh and sixth millennia BP. The oldest group of radiocarbon dates spans from the last two centuries of the eighth to the middle of the seventh millennium BP. They have been obtained from mangrove shell samples retrieved from shell middens discovered mainly along the southeastern shore of the basin. Quite a rapid shift of sites toward its southern edge took place between the end of the sixth and the end of the fifth millennia BP. The radiocarbon results show the progressive desiccation of the ancient lagoon, which would

Shell Middens of the Arabian Sea, Fig. 7 A view of the southeastern shore and the depression of Lake Siranda taken from the shell midden of SRN-63. (Photograph by P. Biagi 2013)

have lost its connections with the Arabian Sea most probably around the end of the fifth millennium BP (see above). This fact is demonstrated by the most recent radiocarbon date obtained from a shell midden discovered inside the southernmost edge of the basin (SRN-57, GrA-57533, 4315 ± 35 BP). This assay can be compared with other radiocarbon dates from mangrove shells obtained from the multilayered Chalcolithic-Bronze Age mound of Balakot (Shaffer 1986) located at the northern edge of the fertile Kurkhera Plain, north of the Winder River course.

The Coast Between Ras Gadani and the Hab River Mouth (Cape Monze/Ras Muari)

The coastline south of the Bay of Sonmiāni is a long sandy strip interrupted only by the rocky headlands of Ras Gadani and Ras Phuari. The first is rich in dark red chert outcrops that were exploited by prehistoric communities at least since the beginning of the Mesolithic. Ras Gadani belongs to the Bela Ophiolite, a sequence of basaltic pillow lavas, inter-flow sedimentary rocks (chert, argillite, and limestone) mostly of Upper Cretaceous age emerging as the western part of Mor Range, and the Parh limestone formation (Upper Cretaceous), a unit of the Pab Range. Farther south, the shell middens discovered along the small, well-sheltered Bay of Daun (Biagi et al. 2013) are distributed partly close to the sand beach that delimits the southern shore of the bay, ca 4–10 m above the maximum level reached by the tide, partly at the top of the neighboring Pleistocene marine terrace 16–20 m high that extends south of a small headland. Their distance from the present coastline varies from 60 to 700 m. Most sites consist of heaps or scatters of small fragments of *T. palustris*, *T. telescopium* mangrove gastropods among which anvils and knapped stone artifacts have been collected (see site Daun-1, for instance), as well as marine bivalves and other species, though a few larger shell middens are also present (Fig. 8). According

Shell Middens of the Arabian Sea, Fig. 8 The shell midden of Daun-4 from the south. (Photograph by P. Biagi 2000)

to the radiocarbon chronology, they are to be subdivided into two main groups: the first to be attributed to the Neolithic and the second to the Bronze Age.

South of the Hab River mouth, in Sindh, at the top of a saddle ca 30 m high, near the fishers village of Sonari, some 7 km northeast of Cape Monze (Ras Muari), Chalcolithic-Bronze Age fishers built rectangular stone structures whose floors are covered with valves of *Meretrix* marine shells, other marine bivalves (mainly *Anadara rhombea*), and fragments of mangrove gastropods (Fig. 9) collected from a tidal forest most probably growing along the southern bank of the river mouth. Sonari is the only Chalcolithic/Bronze Age fishers and mollusk gatherers village so far discovered all along the northern coast of the Arabian Sea. The material culture remains found at Sonari are represented by notched net sinkers made from beach pebbles, anvils, pestles, one quern, and other ground stone implements, a few ceramic potsherds, and knapped stone tools made mainly from good-quality red chert collected from the neighboring Ras Gadani outcrops (Biagi et al. 2020).

These data summarize the information at present available for Las Bela coastline. It would be very important to complete the archaeological project; continue the surveys all along the southwestern palaeoshore of Lake Siranda, in order to explore also the (mobile) sand dunes that separate the sabkha depression from Miāni Hor; and investigate also the northern coast of the Sonmiāni Bay. The latter has been the subject of a one-day survey carried out in January 2012 along its eastern edge. It led to the important discovery of a thin, though continuous horizon of *Zootecus* cf. *chion* land snails located at the bottom of a sand dune deposit, whose radiocarbon dating yielded an unexpected fifth millennium BP assay, with a negative $\delta^{13}C$ (-1.14), a result that needs to be better explained (MHOR, GrA-62258, 5700 $\pm$ 40 BP).

Other problems to be solved regard the absence of fishbones from all the shell middens so far

Shell Middens of the Arabian Sea, Fig. 9 The Bronze Age Fishers' site of Sonari at the Hab River mouth (Sindh). (Photograph by R. Nisbet 2013)

discovered around Lake Siranda and the Bay of Daun. In a few cases, fish otoliths have been collected as well as net sinkers (only five from four different sites from Siranda and two from Daun) and very few crab claws belonging to *Scylla serrata*, a typical tropical mangrove species, though no fish hooks or gorges have ever been recovered. It would be important to radiocarbon date the otoliths retrieved from the surface of five sites that belong to only two marine fish species (*Plicofollis tenuispinis* and *Protonibea diacanthus*) and compare the results with those obtained from the mangrove shells dated from the same site by Groningen University isotope research laboratory, following identical procedures.

Another problem still to be solved regards the location of the lithic raw material sources exploited for the manufacture of the knapped and ground stones artifacts collected from the surfaces of the Siranda shell middens. We know that the poor, though very good, dark red chert outcrops of Ras Gadani were exploited for the production of a great variety of knapped stone tools among which are characteristic geometric microliths (lunates and trapezoidal implements) as well as straight microdrills. We also know that the Ras Gadani knappable resources cover a maximum distribution radius of ca 100 kms north and east of the outcrop. Some of the questions still to be answered are: Where are the outcrops exploited to manufacture the other lithic implements retrieved from the Siranda Lake middens found? What do they represent? Relatively long or short distance movements? The general impression is that they might come from one or more of the so far unknown limestone deposits to be searched in Balochistan (Las Bela mountains of the Kirthar range?) or Jhalawan, as reported by A.W. Hughes (1878), undoubtedly not from Sindh, whose knappable lithic resources are well-known since a few years thanks to the discoveries made by the Italian Archaeological Mission in Lower Sindh (Ongar and Jhimpir). What do we know of other sites eventually located farther inland from the

Shell Middens of the Arabian Sea,
Fig. 10 Location of the Indus Civilization site of Pir Shah Jurio (yellow dot), at the edge of a terrace located along the left (southern) bank of the Hab River, where a mangrove swamp flourished during the Bronze Age. (Drawing by P. Biagi)

Lake Siranda shores attributable to a time period comprised between the Neolithic and the Bronze Age? And where did the seasonal mollusk gatherers of Lake Siranda come from? Where are their more permanent sites located?

Recently, it has been pointed out that our knowledge of the prehistory of Balochistan is far too poor, especially as regards the problem of the origin of the Neolithic, and that the absence of radiocarbon dates from interior territories makes its study very problematic (Shaffer 1986). What are the relationships between the sites located along the Arabian Sea coast and the famous though far too poorly radiocarbon dated aceramic site of Mehrgarh in northeastern Balochistan, along the course of the Bolan River? We know that Mehrgarh inhabitants exploited marine resources mainly to make shell ornaments, most probably during the eighth–sixth millennia BP. Did the two regions entertain some kind of relationships during this period, as the presence of marine ornaments made from small (*Conus* and *Cipraea*) and large oceanic shells (e.g., *Turbinella pyrum*) would suggest?

One more problem to be solved regards the chronology of the disappearance of mangal environments from Lake Siranda. The available data show that this event took place when the Bronze Age Indus Civilization began to decline, roughly around the very beginning of the second millennium cal BC. It would be important to better correlate the chronological results available from the mangrove shell sites discovered around Lake Siranda; Miāni Hor; the Chalcolithic/Bronze Age mound of Balakot; the small Indus city of Pir Shah Jurio (Fig. 10), along the lower course of the Hab; and the fishers site of Sonari, close to Cape Monze in southwestern Sindh, to improve our knowledge of the presence and exploitation of mangal resources in the area also during the Bronze Age and contribute to the interpretation of the environmental/climatic changes that might have contributed to the decline and collapse of the urban, Bronze Age Indus Civilization (Biagi et al. 2016: 12).

The presence of prehistoric shell middens and *T. telescopium* mangrove shell scatters has been recorded also along the Arabian Sea coast of neighboring Sindh, from Karachi, in the west, to Thatta and the Makli Hills, in the east. The radiocarbon chronology of the sites spans from the middle of the eighth millennium BP to the third millennium BP. Shell heaps of mangrove and marine food refuses have been systematically recorded also from the top of all the limestone terraces and sandstone hillocks rising from the alluvial plain of the Indus, at an altitude of

15–40 m above the present sea level. These discoveries contribute to the reconstruction of the progressive advance of the Indus River delta, at least from the Neolithic to the Bronze Age, and to the study of the ancient mangrove swamps that flourished in the delta region at least until the Chalcolithic Amri culture period. Most of the shell middens and sparse scatters of marine or mangrove shells discovered along the (ancient) coast of Lower Sindh are located ca 30 km from the present seashore and in one case more than 80 km from the mouth of the most important Indus channel (Biagi et al. 2016: 17).

Current Debates and Future Perspectives

The archaeology of the two coasts of the Arabian Sea discussed in this paper started to develop around the end on the 1970s near Muscat, in the Sultanate of Oman, more precisely in the mangrove swamp of Qur'm and its surroundings. Since then many things have changed. A region that was considered remote and marginal from any archaeological points of view, reported almost exclusively as the coasts of the fish eaters (*ichthyophagoi*) in the classical literature (Schoff 1974), is nowadays greatly developed within the general picture of the archaeology of the entire Indian Ocean (see, for instance, Cleuziou 2004).

The research promoted since 2000 along the coast of Las Bela in Balochistan yielded evidence of mid-Holocene shell middens also in this remote area (Biagi et al. 2016). Their absolute chronology and environmental location are similar to those known from the coast of the Sultanate of Oman, though one can notice great differences between the sites of the two areas. They regard, for example, the presence/absence of habitation and other type of structures among which are graveyards and tombs, thickness/thinness of the stratigraphic sequences, and presence/absence of faunal (especially fish) and material culture remains among which are ceramic potsherds (Berger et al. 2013; Biagi et al. 2016). Regarding the knapped stone assemblages, there are no technological and typological similarities between the finds from the two coastlines that are to be regarded as resulting from two absolutely different traditions. This fact indicates that the two areas were not in contact at least during the Neolithic and the Chalcolithic. They started to develop only around the beginning of the Bronze Age Indus Civilization when transoceanic navigation and trade began. Nevertheless, the presence of marine shells at the top of a few limestone terraces rising from the alluvial plain of the Indus in Lower Sindh, radiocarbon dated to the beginning of the seventh millennium BP (Biagi 2013: Table 1), and the discoveries recently made at Masirah Island in Oman suggest that coastal navigation took place already in this period (Charpentier et al. 2013), though transoceanic contacts started only around the beginning of the Bronze Age. Evident indicators of Neolithic navigation, in the form of both material culture remains and bitumen fragments, have been retrieved from the Neolithic site of As-Sabiyah in Kuwait along the northwestern coast of the Arabo/Persian Gulf (Carter 2006).

The absolute chronology of the Arabian Sea shell middens has greatly improved during the last decades thanks to systematic programs of radiocarbon dating. Those regarding the sites of Balochistan and Sindh are especially important because all dates have been obtained from the same laboratory, and the shell samples (mainly from *T. palustris*) have been processed to develop a precise chronology of the shell middens of the region in relation to the presence of mangrove environments. This approach greatly contrasts with that developed in Oman, where different laboratories and materials have been utilized from time to time mainly during the last two decades, to contribute to the solution of specific or local problems or to try to define the reservoir age to employ to calibrate mangrove or marine shell dates, though with contrasting results. It is well-known that shells are problematic to calibrate and that the mangrove and marine shells show quite different $\delta^{13}C$ percentages. Nevertheless, the results so far obtained show that the first shell middens started to be settled during the last centuries of the eighth millennium BP both in Las Bela, where the Lake Siranda site SRN-43 was

dated to 7200 ± 35 BP (GrA-54290: Biagi 2013), and the Sultanate of Oman (see SWY-11 at Suwayh, Pa-1716: 7275 ± 60 BP: Lézine et al. 2002: 222). These data reinforce the impression that important changes started to take place along the coasts of this part of Arabian Sea during the last centuries of the eighth millennium BP when the first shell middens make their appearance.

Many problems are still to be solved regarding the shell middens of the Arabian Sea coasts. It is well-known that shell middens are a world phenomenon of which little is known and even less studied and understood, with just few exceptions. The two cases presented in this paper perfectly fit into the above general pattern. The contrasting evidence at present available from the two regions is exemplary in this respect. It also shows the different approaches followed by archaeologists in the two areas and the similarities achieved, for example, in the study of the way the two coastlines developed since the beginning of the Neolithic. Regarding the coast of Las Bela, more surveys are necessary to continue the research west of Lake Siranda. We know that shells were found and radiocarbon dated along the coast of Makran, at Pasni, for instance (Sanlaville et al. 1991), though we do not have any data regarding the presence of real shell middens in the area. Another problem to be solved is that of the Sonmiāni Bay where an important mangrove swamp is flourishing still nowadays. When did it start to develop and where? How did it move through time? Are there shell middens along the northern coast of the bay? Unfortunately, this important area has never been investigated by archaeologists. Regarding the Sultanate of Oman, though the research has greatly improved during the last two decades, mainly thanks to the work of the French Archaeological Mission, a systematic program of radiocarbon dating of the shell middens is absolutely necessary as is the detailed publication of many sites excavated since the beginning of the 1980s.

Sherratt, Andrew

Alexander A. Bauer
Department of Anthropology, Queens College, CUNY, Flushing, NY, USA

Basic Biographical Information

Andrew Sherratt was a prehistorian whose regional focus was Europe and Eurasia but whose wide-ranging command of archaeological data and interest in large-scale (even intercontinental) questions and syntheses made him an Old World prehistorian rare in contemporary archaeology. He earned a B.A. in Archaeology and Anthropology at the University of Cambridge in 1968. He continued his graduate studies there and completed a Ph.D. in 1976 on the Bronze Age in the Balkan region, under the guidance of David L. Clarke, whose students at that time included Robert Chapman, Norman Hammond, Ian Hodder, and Stephen Shennan.

Beginning in 1973, Sherratt took up residence at the Ashmolean Museum, Oxford, where he

served as Assistant Keeper of Antiquities. His service at Oxford far exceeded what that title suggests, as he was a central figure in the university's archaeological community, such as when he helped establish its joint archaeology and anthropology program in 1993. In 1996, he was named a recipient of the McNeill Erasmus Prize for his contributions to European prehistory. Sherratt was finally made a Reader in Archaeology at Oxford in 1997 and Professor in 2002. In 2005, he moved to the University of Sheffield to assume a new Chair in Old World Prehistory, a move that seemed to promise new opportunities until he died suddenly from a heart attack in the spring of 2006.

Major Accomplishments

The breadth of Sherratt's work resulted in his making significant contributions on a wide range of subjects in archaeology, including European prehistory, plant and animal exploitation, ancient trade and exchange, history of drugs and alcohol, climate and environmental change, and archaeological theory. He is perhaps most widely cited for his wide-ranging analysis of the "secondary products revolution," referring to formative use of animals for their renewable products such as milk, wool, and traction and its impact on human society (Sherratt 1981). The data-rich yet sweeping perspective he took in that analysis was characteristic of his work, so much so that he was often compared to his intellectual forbear, V. Gordon Childe, whose contributions Sherratt both sought to defend and reassess through his own collection of essays on European prehistory (Sherratt 1997).

Inspired by both Childe and Clarke, Sherratt spent much of his energy focusing on the "big" questions of European prehistory – from the beginnings of agriculture and the spread of farming into Europe to first use of iron and coinage in the Mediterranean – but his perspective on these questions combined his predecessors' ideas into an approach that was unmistakably his own. As exemplified by his work on "secondary products," Sherratt was drawn to the study of technological and economic innovations and their impact on society as a whole and would use both his deep grasp of archaeological data and cross-cultural analogy to make his case. Like Childe, he explored how such innovations spread from neighboring regions through communication and trade networks, thus seeking a reengagement with diffusion as an important explanatory idea long after it had fallen out of intellectual favor. Through all his work, Sherratt remained dedicated to the idea that the "Grand Narrative" was important for archaeology and that archaeology was uniquely situated to facilitate such long-term and large-scale syntheses (Sherratt 1995).

Sherratt's interest in long-term and large-scale processes led him to explore the potential of a range of models and tools for archaeological analysis. He had a great interest in the potential of world systems analysis for archaeology, critically thinking through the concept and focusing on dimensions neglected in other archaeological engagements, such as the "margin" between "cores" and "peripheries" and the role of consumption as an instigator of contact and social change (Sherratt and Sherratt 1991; Sherratt 1994). More recently, he turned to geographic information systems and the growing availability of high-resolution satellite imagery for mapping and modeling settlement patterns and interregional route systems (Sherratt 2005), and he began an innovative project at Sheffield called "ArchAtlas" to explore their potential (see www.archatlas.dept.shef.ac.uk).

Shinnie, Peter L.

Anna Lucille Boozer
Department of History, Baruch College and The Anthropology Program, The Graduate Center, City University of New York, New York, NY, USA

Basic Biographical Information

Peter Lewis Shinnie (18 January 1915–9 July 2007) was one of the founders of African archaeology (Fig. 1). He developed a particular focus upon Sudan and is best known for the 11 seasons he spent excavating at Meroe, the capital of the Meroitic Kingdom. Shinnie was also a pioneer in archaeological, ethno-historical, and linguistic research in West Africa and particularly in Uganda and Ghana.

Shinnie was born in Wimbledon near London, where he attended Westminster School. According to Shinnie, he was distantly related to John Garstang, another Sudan scholar, whose sister married Robert Gurney, a relative of Shinnie's mother (Grzymski 2007). When he was 12 years old, Shinnie became captivated by H. G. Well's chapter on Egypt in *The Outline of History*. Inspired, Shinnie saved up the two guineas required to purchase Gardiner's recently published *Egyptian Grammar* and began to teach himself the hieroglyphic script. At the age of 14, Shinnie joined the Egypt Exploration Society. In 1933, when he was 15 years old, Shinnie was introduced to the eminent Egyptologist F. Ll. Griffith who advised him not to study Egyptology because the career prospects were bleak (Bradley and Robertson 2007). Shinnie ignored this advice.

Shinnie, Peter L., Fig. 1 Peter Lewis Shinnie portrait photograph of the faculty and staff at the University of Calgary, September 1971 (University of Calgary Archives 84.005_10.04)

Shinnie's first training excavation was in 1934 at Maiden Castle, Dorset, with Mortimer Wheeler (Fig. 2). During four seasons at Maiden Castle, Shinnie learned Wheeler's box method of excavation, to which he remained dedicated for the duration of his archaeological career (Shinnie 1990). He later read Egyptology at Christ Church, Oxford (1934–1938), studying under B. G. Gunn (Bierbrier 2012), and achieving a third-class degree. While at Oxford, Shinnie participated in numerous undergraduate activities: he became an

Shinnie, Peter L., Fig. 2 Peter Lewis Shinnie with Mortimer Wheeler at Maiden Castle, Dorset, England (*ca.* 1934–1938) (University of Calgary Archives 2013.029_1.06)

active member (and later president) of the University Archaeology Society, joined the University Communist club, learned to fly in the University Air Squadron, and attended lectures on Comparative Ethnography at the Pitt Rivers Museum (Shinnie 1990). After graduating from Oxford, Shinnie had to choose between a position on H. W. Fairman's excavations at Amara West in Sudan and one as a full-time organizer for the Communist Party at three pounds per week. Shinnie chose the latter (Bradley and Robertson 2007).

After less than a year as a Communist Party organizer, Shinnie returned to archaeology with an appointment at the Ashmolean Museum as a temporary assistant. When war broke out in 1939, he was called up to the Royal Air Force to fly bombers. Shinnie was a useful resource for the war effort since he already had done his first solo flight in June 1936 (Grzymski 2007). In September 1940, before leaving England, he married Margaret Cloake. Most of Shinnie's active service took place in North Africa, Italy, and Greece. He also served in intelligence, working on aerial photography interpretations and selecting sites not to bomb due to their archaeological significance (Shinnie 1990; Clark 2007).

After the war, he returned to the Ashmolean Museum as an Assistant Keeper (1945–1946) and excavated at the Bronze Age site of Tell Atchana in Turkey with Sir Leonard Woolley. Shinnie began to learn Arabic at this time due to the site's proximity to the Syrian border (Bierbrier 2012). By the time of his death, he was proficient in Arabic, Greek, French, and Italian, as well as numerous ancient languages, such as Ancient Egyptian, Coptic, Meroitic, and Old Nubian (Grzymski 2007). Fascinated by Nubian linguistics, Shinnie also edited a grammar and lexicon of the Nubian language.

Shinnie's first permanent post in archaeology was as Assistant Commissioner for Archaeology in Anglo-Egyptian Sudan (1946–1948). He later succeeded his boss, A. J. Arkell, as Commissioner for Archaeology (1948–1955) (Bierbrier 2012). At Amara West, he had his first experience as an excavation director, followed by research at Soba, Tanqasi, and Ghazali. While on leave, Shinnie conducted research abroad, including a survey in Euboea, Greece (1951, 1952), and an excavation at Kouklia, Cyprus (1953) (Grzymski 2007). He carried out a vigorous publication practice alongside his research and continued the occasional paper series inaugurated by Arkell. Among his accomplishments as Commissioner for Archaeology, Shinnie acquired Flinders Petrie's library for the museum and hired Negm el-Din Mohammed Sherif, who later became Commissioner for Antiquities.

With Sudan's independence in the mid-1950s, Shinnie's post was "Sudanised" (1955). Upon the loss of the Commissioner for Archaeology post, Shinnie returned briefly to the Ashmolean

Museum (1955–1956) before becoming the Director of Antiquities, Uganda (1956–1958). He then moved on to become Professor of Archaeology at the University of Ghana, Legon (1958–1966), with a brief sabbatical break as a Visiting Professor at the University of Birmingham in England (Grzymski 2007). While in Ghana, Shinnie created the first archaeology department in sub-Saharan Africa. He also founded the University of Ghana's Institute for African Studies in 1959 and acted as its first director until 1961. Shinnie organized archaeological expeditions in Sudan that included Ghanaian students, working mainly on the medieval period on the Nubian stretch of the Nile before it was flooded by the Aswan High Dam (Professor Peter Shinnie: A Leading Africanist who promoted archaeology in the sub-Sahara 2007). Among these UNESCO expeditions, his research at Debeira West is particularly well known. The eminent historian Abu Boahen joined him on this excavation while still a young scholar.

Shinnie returned to Sudan and took up a professorship at the University of Khartoum (1966–1970). During this period, Shinnie conducted the research he is best known for: his excavations at Meroe (1965–1984, intermittent), which began while he was still based at the University of Ghana. These excavations were distinct from contemporary ones because Shinnie explored the urban layout, houses, and industrial installations in addition to temples and other monumental structures. He improved his Arabic and spoke it nearly fluently.

By the late 1960s, Shinnie decided that he needed a post that would provide him with a generous retirement. After a single term at the State University of New York at Buffalo, Shinnie moved to the University of Calgary in Canada as Head of the Archaeology Department and his final professorship (1970–1980) (Calgary Archives) (Fig. 3). In the mid-1980s, Shinnie decided to terminate his excavations in Sudan due to his objections to the political climate (Calgary Archives). While at Calgary, he continued his research in Ghana, namely, at the sites of Asante-maso and Daboya. Together with his second wife, Ama Owusua Nantwi Shinnie, he also investigated the origins of the Ashanti by combining research on archaeology, history, and oral history. He sustained active research and student mentorship even after his retirement in 1980.

Shinnie, Peter L., Fig. 3 Peter Lewis Shinnie portrait photograph of the faculty and staff at the University of Calgary, March 1983 (University of Calgary Archives 84.005_41.32_1)

Following his retirement, Shinnie's long career in archaeology gained substantial recognition. In 1983, the University of Calgary warded him an honorary doctorate in appreciation of his contributions to archaeology and to the University. At the Nubiological Congress, held in Geneva in 1990, Shinnie was unanimously elected the Honorary Patron of the International Society for Nubian Studies and presented with an issue of the Society for the Study of Egyptian Antiquities Journal published in his honor. In 1992, his Africanist colleagues presented him with a Festschrift, *An African Commitment*. A final honor was conferred upon him in 2006 when he was awarded the Order of the Two Niles by the government of Sudan.

Throughout his career, Shinnie was deeply invested in an archaeology of inclusivity. He founded the journal *Kush* (1953), an important journal for specialists working in Sudan. Shinnie then founded and edited *Nyame Akuma,* which later became the newsletter for the Society of Africanist Archaeologists. Shinnie insisted that

Nyame Akuma should be sent free to Africa so that his African colleagues could keep abreast of international research. Equally, Shinnie supported the research of African archaeologists while he was based at the University of Calgary (Professor Peter Shinnie: A Leading Africanist who promoted archaeology in the sub-Sahara 2007). Shinnie also ensured that the pamphlets that he produced on Sudanese archaeology and history be available in both English and Arabic. Through these endeavors, Shinnie aimed to knit together scholars from around the globe in a manner that would foreshadow open access publishing.

Shinnie's long career spanned many different phases of archaeological research since he worked for the duration of his long life. Every one of his site reports was published; a rare accomplishment in archaeology. He was aided in these endeavors by his first wife, Margaret Shinnie, and by his students and colleagues, such as N. Chittick (el-Ghazali), R. Bradley, and J. R. Anderson (Meroe). At the time of his death, he was in the process of editing a Nubian dictionary that he had researched with one of his students (A. Osman). In addition to his passion for archaeology, Shinnie spent his leisure time enjoying literature, jazz and classical music, food and wine, travelling, and good conversation (Bradley and Robertson 2007). Shinnie died in Calgary on 9 July 2007 at the age of 92.

Major Accomplishments

Shinnie amassed a large number of research, educational, and outreach accomplishments over the course of his long career in archaeology.

With respect to research, Shinnie served important roles in African antiquities services; he was the Assistant Commissioner and then Commissioner of Archaeology in Anglo-Egyptian Sudan and later served as the Director of Antiquities in Uganda. Shinnie's 11 seasons of excavation at Meroe, Sudan is perhaps the best known of his many excavations. In Sudan, he also pioneered scholarship on the Nubian language and promoted the study of its medieval archaeology. In Ghana, Shinnie combined archaeology and a study of oral traditions to develop a picture of the Asante state from the ninth century onward.

It is especially notable that Shinnie promoted the roles of Sudanese and Ghanaian archaeologists through the foundation of formal educational programs in their home countries. In doing so, Shinnie founded the first archaeology department in sub-Saharan Africa. In the 1960s, Shinnie created a diploma in archaeology at the University of Khartoum and trained three of the pioneers in the Sudan Antiquities Service at Royal City of Meroe. As part of this degree program, Shinnie recruited Dr. Steven Green to the Department of History at the University of Khartoum to teach honor degree students in ancient history (1968–1970). Shinnie sustained his commitment to these students even after relocating to Canada. From the first cohort of University of Khartoum archaeology students, two subsequently attended the University of Calgary to complete MA degrees in archaeology.

In recognition of Shinnie's foundational research and commitment to the archaeology of Sudan, he was awarded Sudan's Order of the Two Niles in 2006.

Ship Archaeology

Seán McGrail
University of Southampton, Southampton, UK

Introduction and Definition

Ship Archaeology is that subset of Maritime Archaeology that deals with water transport: floats, rafts, boats, and ships. By the analysis and interpretation of excavated remains, archaeologists trace the origins of such vessels, their function, how they were built, propelled, steered, and navigated, the harbors they used, and the origins and destinations of the cargo and the people that they carried. Those who specialize in this subject have to be multidisciplinary: In addition to archaeology and/or history, a sound understanding is needed of seafaring, navigation, naval architecture, woodworking techniques, ancient climates, and former sea levels.

Historical Background

During past millennia, lakes have altered their bounds, and rivers changed their courses; sea levels have varied, thereby altering coastlines, and latterly there have been large-scale drainage projects. Nowadays, therefore, ancient vessels may be found not only in seas, rivers, and lakes, but also on what is now land. Some vessels were ritually deposited – for example, one of the oldest plank-built vessels in the world, Pharaoh Cheops' ship of c. 2,600, BCE, was found entombed in the Egyptian western desert. Furthermore, five medieval ships excavated at Skuldelev in Roskilde Fjord, Denmark, that were subsequently published in standard-setting volumes by Ole Crumlin-Pedersen, had been reused to block sea inlets against invaders. Nevertheless, the majority of excavated, seagoing vessels are found to have been wrecked inshore or in deeper water, or abandoned on what was then the foreshore. River and lake boats (for example, simple logboats) are usually excavated from the environment in which they had been used.

In the intertidal zone, excavation tactics have had to be developed to cope with the conditions encountered underfoot and with the varying stages of the tide. Reliable excavation underwater has been possible only since the post-WW2 development of diving gear and of specialized surveying and excavation techniques.

Related Disciplines

Early accounts and representations of water transport have the potential to increase understanding of excavated remains, but that enhancement may not amount to much. It is often difficult, and sometimes impossible, to understand details depicted in early drawings and carvings. Moreover, chroniclers' accounts are usually general in nature, and, even where boats are mentioned, the technological information derived may be minute. On the other hand, technical instructions compiled by ship builders are of exceptional importance, the earliest known being published in sixteenth century CE Venice. Useful accounts have also come down to us from travelers and explorers who were familiar with boats. In recent times, traditional boats have been described in detail as a result of ethnographic fieldwork. Such accounts have proved useful in the interpretation of enigmatic features found on excavated vessels.

The theoretical reconstruction of former environments is essential to a full understanding of

each maritime site. Early sea levels and the former run of coastlines and rivers must be ascertained so that a picture is obtained of the environment in which the vessel was wrecked or abandoned. Furthermore, "back-casts" of ancient tidal flows, currents, and weather patterns (especially predominant winds) provide a guide to the sailing conditions prevailing in former times.

Key Issues/Current Debates

Archaeological Research

The focus of ship archaeological projects is initially on the site itself, supplemented by related information drawn mainly from the fieldwork experience of the excavator. Subsequently, research shifts to the laboratory where samples from the excavation are identified and dated, and the constituents of substances such as fastenings, tar, and paint are determined. After the remains have been recorded on site, they are lifted, either as a coherent whole or timber by timber, and stored in water within a specialized laboratory where, before active conservation, each component is recorded by measured drawing, photograph, and written description. The timbers are conserved by spraying with, or immersion in, polyethylene glycol; alternatively, or in addition, freeze-drying may be used. Other methods under development include the use of sucrose, and impregnation with a resin which is then cured. Whichever method is chosen, the process (including the final drying phase) may take years, even for a medium-sized vessel.

While the timbers are being conserved, an "as-found" measured drawing of the vessel is compiled using the results of the recording process. This drawing depicts the remains as they were when excavated, but with displaced timbers reinstated, distorted timbers realigned, incomplete and fragmented timbers made whole, and the resulting structure rotated until it is orientated as was the original vessel when in use. A small-scale model (Fig. 1) may then be built from this "as-found" drawing and used to investigate whether it is possible to reconstruct – in a theoretical way – the complete hull of this vessel: Insufficient surviving evidence may make this impossible. A valid reconstruction of the original form and structure of the hull is likely to result when:

- (Most of) both ends of a boat have survived, or one end survives and it can be deduced that the boat had been "double-ended"
- Articulated runs of planking survive, up to an undoubted sheerline and/or sufficient framing survives to define the outline of the hull

During such reconstruction, wishful thinking must be avoided: Only those features that are supported by rigorous argument should be added to the "as-found" scale drawing. It is valid, for example, to incorporate hull structure and fittings that it is believed are undoubtedly essential and

Ship Archaeology, Fig. 1 "As-found" 1:10 scale model of the Barland's Farm boat, based on measured drawings of all timbers excavated. (Courtesy and copyright of the Newport Museum)

have been documented in a near-contemporary wreck of the same building tradition. When evidence for sail (such as a mast-step) survives on an excavated vessel, contemporary iconographic evidence – if such exists – may assist in the difficult task of determining details of mast, sail, and rigging. At intervals in this process, findings and intentions should be presented to a "jury" of specialists in this type of research. If the final hypothetical reconstruction drawings (Fig. 2) are validated by such a group, they may be used to estimate performance figures. A scale model may also be built which will probably be more informative to the nonspecialist.

When conservation of the excavated vessel is finished, and timbers can be handled, the remains are reassembled in the area in which they will be displayed. This "rebuilding" of the vessel may result in fresh ideas about the hypothetical reconstruction that if validated can be incorporated in another revision of the drawings and model.

Subsequently, if funding can be acquired and working spaces identified, it may become feasible to use these drawings and the model to build a full-scale reconstruction that, after launch and fitting-out, should undergo rigorous sea trials. This process is known as "Experimental Archaeology" and the vessel built and tested is considered to be a "floating hypothesis." The reconstruction and the building of a floating hypothesis of a *trireme* (Fig. 3) – an eastern Mediterranean warship of seventh to fourth centuries BCE – is a (possibly unique) example of such an experimental project that was based almost entirely on documentary and illustrative evidence rather than on excavated remains (Shaw 1993; Morrison et al. 2000).

The most difficult processes in such experiments have proved to be:

Ship Archaeology, Fig. 2 Reconstruction scale drawing of the hull of the Barland's Farm boat. Elements reconstructed may be identified by comparing this drawing with the "as-found" model in Fig. 1. (Courtesy and copyright of the Glamorgan-Gwent Archaeological Trust)

Ship Archaeology, Fig. 3 The "floating hypothesis" *Olympias*: a full-scale reconstruction of a fourth century BCE Greek *trireme*, under sail in the Aegean. (Courtesy and copyright of the Trireme Trust)

- The formulation of the academic aims of the project
- The rigorous production of a reconstruction drawing or model
- After each phase, the submission to external criticism of (a) conclusions drawn and (b) the project's intentions for the next phase

Unless these procedures are satisfactorily undertaken, any hypothetical reconstruction will be invalid, and any vessel built will not be authentic (Bennett 2009: 16–23)

Key Issues

Terminology

In the preface to his classic work *Water Transport*, James Hornell (1946: vii; 1970: xv), observed: there are "many devices upon which men, living in varying stages of culture, launch themselves afloat upon river, lake and sea." Since, in earlier times, every raft or boat was individually built, each one was different in some respect from all others. We therefore need a method of grouping together boats that are generally similar so that patterns may be identified and fundamental shifts in technology recognized.

The primary classification of water transport is into the three classes: floats, rafts, and boats/ships. A *float*'s buoyancy is applied directly to the human body which is part-immersed, whereas the buoyancy of rafts and boats is applied indirectly. How that indirect buoyancy is derived differentiates rafts from boats/ships: Rafts are "flow-through"; therefore, a *raft*'s buoyancy is derived from each floating element of its structure; a *boat*'s buoyancy, on the other hand, is derived from the displacement of water by her continuous, watertight hull. In this context, a *ship* is considered to be a large boat.

It is convenient to subdivide these classes into subclasses identified by the principal material used in their construction:

- Four types of float: log; bundle; hide; and pot – plus, in recent years, oil drums
- Four types of raft: log; bundle; hide-float; and pot-float
- Six types of boat: log; bundle; hide; bark; basket; and plank

Building Sequences

In the mid-twentieth century CE, two sequences, "shell-built" and "skeleton-built," were identified as the principal ways in which plank boats were built (Hasslöf 1963). This distinction can also be seen in bark boats and hide boats. In the "shell-built" sequence (Fig. 4), planking is fashioned and then fastened together to form a watertight hull; framing is then fastened inside that planking. The builder visualizes such a boat as a watertight shell reinforced by framing. This sequence is now known as "plank-first."

In the "skeleton-built" sequence (Fig. 5), framing is fashioned to give the hull shape required; planking is then fastened to that framework. The builder visualizes such a boat as a framework or

Ship Archaeology, Fig. 4 Four stages in the plank-first sequence of building a medieval Scandinavian boat. (Copyright of Seán McGrail, after Ole Crumlin-Pedersen 1983: Fig. 5)

Ship Archaeology, Fig. 5 The frame-first sequence: the framing of a *vattai* fishing boat fashioned to shape and set up in Atirampattinam, Tamil Nadu, before planking was added (Copyright of Seán McGrail)

skeleton made watertight by adding planking. This sequence is now known as "frame-first": It may be further divided into:

- Those built sequentially: first, lower framing, to which planking is fastened; then, upper framing that is then planked. This sequence of building may be described as "framing-first": Such boats are mostly early in date.
- Those that were not planked-up until virtually the entire framework/skeleton had been erected. This sequence is the true "frame-first": Such vessels are mostly from post-medieval times when great ships were built in this way.

Building Traditions

Builders and users today recognize the concept of a "tradition" of building for the range of vessels with which they are familiar. For excavated vessels, it would be desirable to use the original type-names but, even when names have survived, it can prove difficult to link one to specific excavated vessels. In northern Europe, this link has proved possible in one case: The characteristic features of the medieval merchant ship "cog" were deduced from late medieval texts and from depictions on town seals. Using this key, a number of wrecks have been identified as cogs. A principal feature of the cog, and of several other traditions, is the way the planking is fastened together (Fig. 6).

The distinctive boat-and-ship type used by Scandinavians (and subsequently others) from the early centuries CE to the fourteenth century (and later) CE is not precisely named in early texts but in recent times has been known as "Viking." Since this way of building originated before the Viking Age, and continued in use long afterward, it is now described as "Nordic." Excavations, research and publications by Ole Crumlin-Pedersen, during the past 50 years, have greatly added to our knowledge of this boatbuilding style (Crumlin-Pedersen and Olsen 2002).

For other periods and places, it has been found useful to group excavated vessels with similar features into "traditions." A "tradition" may be defined as: "the perceived style of boat-and-ship building generally used in a certain region within a given time range." This concept has increased understanding of the way building techniques have changed over time, and has facilitated the recognition that some traditions have induced changes in the building methods of other regions. Such traditions are artificial groupings constructed by archaeologists after the analysis of each excavated vessel over a wide range of characteristics – mostly structural features such as fastening methods (Fig. 6), but also hull shape, propulsive means, and steering arrangements. It is not necessary that the vessels in each tradition should have all characteristics in

Ship Archaeology, Fig. 6 Plank fastenings. (**a**) Planking lashed together, as in the early, sewn plank boats of southern Britain. (**b**) Planking fastened to the frames of an early centuries CE, Romano-Celtic boat. (**c**) Locked mortise-and-tenon plank fastenings used in early, eastern Mediterranean vessels. (**d**) Early medieval, Nordic fastenings in overlapping (clinker) planking, with hair caulking and nails clenched over a metal rove. (**e**) A Slav variant of (**d**) with moss caulking and treenail fastenings. (**f**) Hooked nail, plank fastenings in the medieval Bremen cog, with moss caulking held in place by metal clamps. (Copyright of Seán McGrail)

common. In a *polythetic* group, each boat shares a large number of characteristics with every other boat in that tradition, but no one characteristic has to be possessed by all boats. In this respect, polythetic groups reflect an understanding of the real world (Doran and Hodson 1975: 160), and should be used whenever possible.

Sewn plank boats, excavated or ethnographic, are known throughout the world (McGrail 1996). The group of prehistoric sewn plank boats is generally undifferentiated, although two broad types have been identified in those excavated in northwest Europe:

- Boats with planks *lashed together* by single stitches through large holes (Fig. 6a)
- Later boats with planks fastened by *continuous sewing* through smaller holes

Other traditions, such as "Romano-Celtic" (Fig. 6b) and "Nordic" (Fig. 6d), which were initially identified by intuitive, ad hoc methods, were subsequently placed on a sound basis using evidence from excavated boats.

Design and Building

It is generally considered that the earliest rafts and boats were built by eye, using "rules of thumb." It seems likely that rafts continued to be constructed in this way into recent times. Boats were probably similarly built (in the plank-first sequence) until the early centuries CE, when there is the earliest evidence for frame-first boats built on a designed framework (see below). In time, and in certain places (for example, Europe and China), the size of these designed boats was increased so that they became ships.

Building Frame-First Vessels

Three, seagoing boats of the first to fourth centuries CE have been excavated: from the River Thames at Blackfriars, London; in St Peter Port harbor, Guernsey; and in a former tributary of the River Severn, at Barland's Farm in southeast Wales (Rule and Monaghan 1993; Marsden 1994; Nayling and McGrail 2004; Oleson 2008: 625–627). From them, distinctive structural features of this Romano-Celtic tradition have been identified, the most characteristic being:

- Absence of plank-to-plank fastenings (Fig. 6b), and no plank scarfs but butt joints at frame stations
- Use of the framing-first building sequence (the earliest known)

These features are clearly different from those used to build prehistoric logboats and sewn plank boats, the only other known types of early European wooden boat. The builders of these Romano-Celtic boats appear to have used a unit of measurement (55–56 cm – possibly two human feet) to space the framing. There may also have been a 1:2:3 ratio between maximum breadth, length of plank-keel, and length overall. Moreover, it seems possible that, before planking, longitudinal battens on a master frame were used to give hull shape. In these, characteristics may be seen the beginnings of a formal design method. Early framing-first builders probably handed on their skills by word-of-mouth as "rules of thumb," since not until the late medieval period do we get written accounts and illustrations of such procedures (McGrail 2001/2004: 160–165; Oleson 2008: 613–625).

It may be that this northwest European frame-first building sequence originated in the building of hide boats. No early hide boat has been excavated, but there is documentary and iconographic evidence for their use in the British and Irish archipelago from the mid-first millennium BCE suggesting that, in earlier times, they had a significant role in northwest European seafaring. From postmedieval accounts, we learn that such boats were built – as they still are today – by covering a wicker framework with hides: first the framework; then the "skin": This is the frame-first sequence.

A similar sequence of construction, but differing in detail from that in the Romano-Celtic ships, was used from the fifth/sixth to the ninth century CE to build several Mediterranean planked vessels excavated from Levant coastal waters. It has been suggested that this framing-first building sequence may have come to mind when replacement planking was fitted to the framing of a plank-first vessel (Kahonov 2011: 161–181).

After the fourth century CE in northwest Europe, and the ninth century CE in the Mediterranean, there is, at present, no sign of the frame-

first sequence until eleventh century when it was used in Asia Minor and in southern Europe; from there, the technique appears to have spread along the coast of Atlantic Europe as far as the Baltic. In the fifteenth century CE, this sequence was used to build the European sailing ships that sailed "all the seas of the world" (McGrail 2001/2004: 245–257). During this period, there also seems to have been a shift to building frame-first in China (Xi and Xin 1991; McGrail forthcoming). Some of the medieval ships recently excavated in Chinese waters may well have been built "bulkhead-first" – a variant of frame-first. Like the medieval European ocean-going ships, the hull shape of these late-fourteenth century CE Chinese ships appears to have been determined by their framework (of bulkheads).

In both China and Atlantic Europe, this significant shift from plank-first to framing-first (possibly around the same time) was followed by ocean-going voyages: into the India Ocean by the seven Chinese fleets commanded by Admiral Zheng Ho, and into the Atlantic Ocean by Portuguese and Spanish ships.

Building in the Mediterranean

Although logboats have been excavated in the Mediterranean region (for example, in Italy), plank boats, subsequently ships, dominate the archaeological record (Oleson 2008: 606–637). The earliest known are from late-fourth millennium BCE Egypt: In addition to sewn fastenings, wooden tenons were used within the plank thickness to link planking together. Sewn plank boats were still being used in the Adriatic until the twelfth century CE. From the fourteenth century BCE, however, the locked mortise-and-tenon joint (Fig. 6c) appears to have become the principal eastern Mediterranean fastening. It continued in use through Greek and Roman times and on into the Byzantine period until it was superseded by framing-first vessels (without plank-to-plank fastenings).

As Roman commercial interests expanded, the use of mortise-and-tenon plank fastening spread over much of the then-known world. Several northwest European vessels of the early centuries CE were built with such fastenings, including a third/fourth century CE boat excavated from Lough Lene in County Westmeath, some 50 miles northwest of Dublin (O'Heailidhe 1992). This fastening has also been found in southeast Asia: on an undated wreck at Johore Lama in Malaya, and during recent excavations in northern Vietnam of a first century BCE plank-extended logboat and a second century CE boat planking reused in a coffin (Bellwood et al. 2007).

Boat Operations

Steering and Propulsion

Rivers may be obstacles to land travel (hence the development of fords and ferries) but they can also be used as "highways" across land to the sea. Drifting downstream would have been unreliable until a means of steering had been devised – paddles (examples of which have been excavated from European Mesolithic sites), poles, and oars could have been used to steer as well as to propel. Rudders differ from other means of steering in that they are fastened to the hull of the boat and are rotated by the helmsman around their own, near-vertical axis. There are two types: side rudders fastened to the boat's hull on one (sometimes both) quarter(s); and median rudders fastened at the stern. When the helmsman rotates a rudder so that its aerofoil section blade lies at an angle to the water flow, a horizontal force is generated in the water at the stern; this force causes the boat to turn until the rudder is returned to its neutral position.

The problem of returning upstream against the current was solved in early Mesopotamia by rowing and by towing, the latter from an oared tug or by a team of men walking along the river bank. In Egypt, on the Nile below Aswan where there was generally a northerly wind, sail was used to overcome the northward-flowing current, and propel boats southward. Depictions of the use of sail, dated 3,000–4,000 BCE, have been excavated in Egypt, but earlier evidence has recently been excavated from a site in Kuwait (Carter 2006): a vessel with a bipod mast on a ceramic disc dated sixth to fifth millennium BCE (Fig. 7).

Ship Archaeology, Fig. 7 A painted ceramic disc from Kuwait, dated to the Ubaid 3 period (sixth to fifth MBC), depicting a vessel with a bipod mast. (Copyright of Carter 2006: Fig. 4)

It seems likely that these earliest sails – in both in Mesopotamia and Egypt – could only be used to propel a boat down- or across-wind. How, and when, sailing vessels first made ground against the wind is difficult to determine, but there are indications that it may have been in the second millennium BCE. Interpretation of Egyptian representations of sailing vessels dated to the middle of that millennium suggests that such vessels could have been sailed when the wind was from a point forward of the beam. At around this same time, the methods used to find and settle Oceanic islands appear to have changed significantly. As these pioneering seafarers spread eastward from the western rim of the Pacific, island groups were found to be much more widely spaced. Passages could therefore no longer be undertaken by visual, pilotage methods, and ways of navigating when out-of-sight of land had to be devised (see below – "Early Seafaring"). It may be that at this time, in Egypt as well as in Oceania, a sailing rig was evolved, and procedures established, that resulted in vessels making ground against the wind.

From the dates now given for the earliest depictions of sail in India and China, and in the Eastern Mediterranean, Western Europe, and Scandinavia, it might seem that sail use spread outward from the Egypt–Mesopotamia region through the Mediterranean to Atlantic Europe in the northwest, and through India and SE Asia to China in the east. This may or may not be true, but it is undoubtedly not true that Egypt–Mesopotamia was the sole origin of sail. Early European explorers of the Americas found a range of sail types and rigs on rafts and boats, on both east and west coasts, from the Arctic to Brazil and Peru. Such rigs and sail shapes have no parallels in Europe or elsewhere, and must have had an American origin.

Associated with sail in several European depictions of South American craft was the *guares*, an immersed steering foil or "variable leeboard." These long, wooden boards, of aerofoil cross-section and with a handle at the upper end (Fig. 8), were lowered through gaps between the logs of seagoing rafts. By varying their position and depth of immersion, course could be altered, sailing balance attained, and leeway reduced. Such usage was first noted by Europeans in the eighteenth century CE. Excavated *guares* have been dated to *c*. 300 BCE (McGrail 2001/2004: 401–412).

Sailing Seasons

Periods of storms and of obscured skies were avoided and times of favorable winds used: thus seasonal sailing evolved. In European Atlantic waters, for example, vessels were generally not used on sea passages between mid-October and mid-March; similarly, Arabian vessels avoided approaching the west coast of the Indian subcontinent between mid-June and mid-September. In Roman times, ships sailing for India left Red Sea ports in July so that the southwest monsoon wind would take them across the Arabian Sea in August and September. In late November, the northeast monsoon was similarly used for their return passage. Columbus, heir to much seafaring knowledge, timed his pioneering, fifteenth century CE Atlantic voyage so that he would have a generally following, easterly wind for his outbound passage, and, in more northerly latitudes, a fair, westerly wind for his return to European waters (McGrail 1992).

Ship Archaeology, Fig. 8 Variable leeboards ("guares") excavated from graves of c. 300 BCE, at Ica, Peru. (Courtesy and copyright of the Museum für Völkerkunde, Berlin)

Landing Places and Harbors

In tidal waters, early water transport was used from intertidal beaches where, on each flood (rising) tide, vessels floated. Where beaches and river banks were soft, withies and poles or hurdles and stakes were laid to form a hard. In tideless seas, such as the Mediterranean, on the other hand, vessels were left afloat, at anchor, with their stern moored by line to the shore. Such informal sites are still used in many parts of the world (McGrail 1987/1998: 267–274)

The earliest known harbor walls were built in the eastern Mediterranean during the eighth to ninth centuries BCE to protect landing places exposed to onshore winds and seas. As time progressed, additional features – jetties, lighthouses, silt-dispersal facilities – were incorporated until, by late Roman times, important harbors had many of the facilities seen in nineteenth century Europe. During the tenth to eleventh century CE, as towns in northwestern Europe grew, and economic life became more complex, seagoing ships became bigger. Rather than remaining at anchor, such vessels could more readily be loaded and discharged in deep-water berths, alongside wharfs. These requirements, the state regulation of trade, and the introduction of warehouse marketing methods, all combined to cause a surge in the building of formal harbors at focal points in international networks.

Early Seafaring

There is no direct evidence for any type of water transport before 9,000 BCE, but other archaeological and geophysical evidence demonstrates that Man crossed seas very much earlier (Anderson et al. 2010). Two questions arise about such early voyages:

- What type of water transport was used?
- How did these early mariners navigate?

Water Transport

Since these voyages were undertaken millennia before the date of any excavated example of water transport, it is necessary to work indirectly toward an answer to that first question. Using data from recent examples of all known types of water transport, the technical stage (hence approximate date) appropriate to the building of each one of those types (each with a simple and a complex version) can be estimated. This method suggests, for example, that the settlement of Australia from southeast Asia in Palaeolithic times could have been undertaken in paddled rafts of bamboo logs (Anderson et al. 2010: 95–107).

Navigation

It seems likely that such early overseas migrations were undertaken over a lengthy period from island to island, with succeeding generations undertaking successive legs. On each passage, in that age of lower sea levels, land would always have been in sight, ahead or astern, or both. Thus, *pilotage techniques*, using the human eye, would have

been used to keep track of a vessel's position as she progressed from one island to the next.

From the second millennium BCE, widely spaced groups of Oceanic islands were settled by mariners who must have been out-of-sight of land during much of the passage. It is conjectured that these island groups were first sought on reconnaissance voyages from southeast Asia and from the islands of western Melanesia. Such voyages would have lasted several days during which *deep-sea*, *navigational techniques without instruments* would have been necessary. After these explorers had returned home and thereby "fixed" the position of the newly located islands, settlement voyages in more capacious boats would have been undertaken (McGrail 2001/2004: 339–345).

In the late-twentieth century, Micronesian seaman demonstrated how boats could be navigated without instruments, using methods handed on by their ancestors that are generally similar to those now known to have been used by Arabs and other late medieval seamen. Courses were steered relative to the sea swell or to the wind, or, at night, by reference to specific stars – in the northern hemisphere, especially the Pole Star and its circumpolar constellations. These courses would then be cross-checked during daylight by noting the relative bearing of the sun at sunrise, noon (its highest point), and sunset. The boat's speed was probably assessed by comparison with past performance in the light of the existing wind and sea states, such "speeds" being expressed as "faster" or "slower than usual."

Land may be detected long before it becomes visible, by the sight of cloud sitting over it, by the flight line of birds, and by soundings that reveal decreasing depths of water. The outline shapes of coastlines, especially those with high peaks or distinctive cliffs, would have been memorized for future use. On subsequent passages, navigators would have to identify their actual landfall relative to this known silhouette and thus be able to turn along the coast toward their intended destination. The accuracy of this "navigation without instruments" has been demonstrated during sea trials in which Micronesian navigators, monitored by Australian and American observers, used such methods on Oceanic passages out-of-sight of land.

Future Directions

In conjunction with documentary, iconographic, and ethnographic evidence, excavations have thrown light on the building and the use of the early plank boats and ships of Egypt, the eastern and central Mediterranean, and the European Atlantic seaboard. Furthermore, in Chinese and southeast Asian waters, several important seagoing medieval ships have been excavated and published. In other regions of the world, however, Boat and Ship Archaeology is, at best, still in its infancy. Moreover, direct evidence worldwide for water transport is strongly biased, there is no evidence of early floats and negligible examples of rafts. Furthermore, evidence for boats is almost entirely limited to those built of planks or of logs.

Water transport is its own advertisement: Through the ages, boatbuilders everywhere have been influenced by nearby building traditions, or by the traditions of overseas trading partners. To understand fully the ancient water transport of any one region, a sound knowledge of the ancient vessels of other lands is needed: The early maritime aspects of India, China, and similar regions should be investigated.

By its published research during the late-twentieth to early twenty-first century CE, ship archaeology has attained a recognized place within the archaeological discipline. To consolidate that position, it is now necessary not only to improve fieldwork techniques, but also to make the study of water transport worldwide, and to trace early examples of every type of float, raft, and boat.

Shipyard Archaeology

Lynn Harris
Program in Maritime Studies, East Carolina University, Greenville, NC, USA

Introduction

A growing body of international peer-reviewed research on shipyards published since the 1990s is testimony to the rapid expansion of the discipline beyond the traditional focus on shipwrecks and vernacular watercraft. Analytical frameworks such as maritime cultural landscapes and maritimity, regional and global approaches, ship graveyards, shoreline, and port studies are conducive to the inclusion of shipbuilding and repair facilities (Pastron and Delgado 1991; Pitt and Goodburn 2003). The bulk of the yards that scholars have investigated are located in proximity to active ports in urban areas. The multiple footprints of these sites in the archaeological record, both on land and underwater, are commonly wharves, slipways, docks, sawpits, sandpits for kiln work, warehouses, and specific tools and machinery associated with the shipbuilding process. Researchers have addressed a colorful cross section of themes related to shipyard archaeology including critiques of archaeological methodology, recycling ship parts, innovation and technology, gender, ethnicity, labor, and land use. Management of shipyard sites are associated primarily with concerns about rapid urban development along inland waterways and ports, coupled with lack of training of cultural resource

managers to either identify or document these sites (Stammers 1999; Ford 2006; Richards 2008; Harris 2010; Moser 2011).

Definition

A shipyard, generally situated close to the water and building resources, is an industrial site closely linked with labor history and current socioeconomic events. It represents the crucial connecting piece between the product – the ship – manufacturers or shipbuilders, society, and environment in which the ship is designed to operate. There exists a wide variation in the size of the shipyard, services the shipyards offered, and how the yard conducted primary shipbuilding functions through time. Some were located inland on rivers at small towns and others served larger cities and ports.

Moser (2011) proposes a useful typology dividing shipyards into five broad categories or tiers: (1) large state-owned and operated yards like the naval British dockyards of the eighteenth and early nineteenth centuries, (2) well-organized private yards with a large labor force like the Dutch East India Company operatives in Amsterdam, (3) private yards with a substantive labor pool that could build multiple vessels at the same time, (4) smaller private shipyards with single slipways that could only build or repair one vessel at a time such as Wicomico shipyard in Maryland, and (5) shipyards with little permanent infrastructure only constructing or repairing a few vessels and often in dire financial straits.

Key Issues and Current Debates

The limitation of a typology is that most yards, in any time period, went through spiraling stages of economic development and decline influenced by a variety of factors, most prominently war and labor issues. Shipyards in category 3 and 4 often had multiple site identities and served a variety of roles for the local community functions beyond shipbuilding. The multifunctional nature of a "shipyard" further complicates interpretation of the archaeological record. Shipyards were both small and big businesses that survived or thrived, went out of commission, partnered reluctantly or enthusiastically with other enterprises, or dabbled in other economic endeavors in addition to shipbuilding to stay solvent. In the North American colonies, for example, the shipyard labor pool was comprised of a potpourri of immigrants, apprentice and itinerate shipwrights often trained in the large European yards, hired plantation slaves, shipyard-owned slaves trained in shipbuilding skills, and free black and white laborers. Shipyards were supported financially, and often precariously, by family still living in Europe, wealthy local colonial and marriage networks, and lucrative skilled partnerships with other shipwrights. One of the key issues in attempts to add meaning to shipyard research is how to discern the signatures of socioeconomic changes in shipyard status through time. Another dilemma is how to tweak out the essence of contributions of women, family networks, and labor pool to the success and failure of shipyard enterprises from the archaeological record. Lacking that dynamic socioeconomic context, shipyard archaeology studies are at best only a descriptive site report or database entry.

Between 2003 and 2004 scholars conducted extensive excavations at the *treasure* shipyard or *boachuanchang* in Nanjing. The yard was utilized actively in a period of China's maritime history during the early fifteenth century when thousands of government-commissioned ships ventured from the mouth of the Yangzi River southwards along the Chinese coast to Southeast Asia and the Indian Ocean. Archaeologists recorded multiple pylons believed to provide stable frameworks for ships under construction. Excavators unearthed an assemblage of around 2,000 artifacts. Among the collection were two rudder posts, both over 10 m long. These artifacts complement the 11.6-m rudder post discovered at the same shipyard in 1957, currently stored in the National Museum of China in Beijing. Iron artifacts included shipbuilding tools like knives, chisels, punches, rings, hoops, picks, and nails. Of interest in the archaeological record for shipbuilding processes were iron staples or *bading*. These straight pieces of iron, with the two ends bent at 90° in the same direction,

were used to fasten wooden joints. The site also yielded ceramic items including a variety of earthenware and porcelain (Nan Jing Shi Bo Wu Guan 1991).

Shipbuilding yards have been identified in Greece, Italy, and Israel (Baika 2003; Blackman 2003; Raban and Linder 1978: 243). Many ships were simply built on the shores of the beaches, like the Black Sea coastline, with easy access to launching. In Turkey thirteenth-century shipyard buildings survived at Alanya on the Mediterranean Coast. Buildings provided an important study in architecture and further knowledge about the types of warships used by the Anatolian Seljuk. The shipyard is situated within a medieval town, cut into the rock on a hill and surrounded by high walls. The enterprise comprises sheds for building and protecting vessels, metal-working areas, and administrative spaces. Productively utilized, the shipyard not only was a place to build and store ships not in use but also provided facilities for repairs, with the additional capability of producing sails and rigging for the navy (Daggullu 2009: 13–20).

Northern European shipyard scholarship is devoted primarily to military shipyards beginning in the 1970s with work by Courtney (1974–1975) at the Royal Woolwich dockyard. This formative study interpreted land use through time while explaining specific uses of facilities for dockyard operations. While industrial facilities comprise a dominant portion of the work, other ancillary features investigated included the surgeon quarters, the clock house, and roadways. Underwater investigations in the 1990s around the Beaulieu River in England, the London and Amsterdam waterfront centered on slipways, which were the most diagnostic underwater component of a shipyard site. Archaeological interpretation encompassed bathymetric and topographic surveys, followed by documentation of the stylistic features of the slipways (Adams 1994; Gawronski 2003).

In North Wales and North West England, Stammers (1999: 253–264) explored a variety of historical shipbuilder records including census records, court records, trade directories, advertisements, artwork, and ordnance maps showing shipyards. The study identified variation in size of shipyards in urban England and the problem of space in working areas. Stammers reinforces the value of shipyards to the archaeological record as important resources that can show evidence of the construction process of shipbuilding, the materials deployed, information about a workforce, and how it transmitted ideas into tangible form. In Ireland, research of maritime landscapes included phase one archaeological surveys and historical documentation of shipyards such as the industry surrounding Portaferry, a leading port for Strangford Lough during the late eighteenth and nineteenth centuries. The town grew around a sixteenth-century tower house, later expanding into a large industrial operation with three yards that could accommodate the construction of an impressive array of ships for the transatlantic trade (McErlean et al. 2002: 220).

To date, most landscape analysis in the southeastern USA has been devoted to plantation sites rather than industrial sites. In a sense, plantations with slaves trained as craftsmen, including boat and shipbuilders, represent a form of rural and private sector industrialization. Studies of coastal and riverine shipyards including Hobcaw shipyard and Mars Bluff shipyard in South Carolina, McKnight yard in North Carolina, and Willink shipyard in Georgia offer pertinent information about the diverse archaeological signatures of southern shipyards in different time periods and geographic locations (Figs. 1 and 2). The case studies reveal that choice of site, location, and layout plan of the work facility are key elements in understanding the operation of the shipyard. Historical records of these three shipyards like naval recommendations, advertisements for land, sale receipts, probate records, and comments of customers all provide keener insights into social perceptions about suitable shipyard locations, the trade-offs of choices, growth, and fiscal stability of shipyard endeavors.

In 1984 investigations at Hutchinson Island in Savannah Harbor included observations of

Shipyard Archaeology, Fig. 1 Artistic impression of Hobcaw shipyard. (Courtesy of Hernandez family)

Shipyard Archaeology, Fig. 2 Caulking tool from Mars Bluff Shipyard. (Courtesy of East Carolina University)

features such as Willink's marine railway, a shipyard in operation from 1873 to 1898; shoreline spoil edge; and extensive brick scatter. Archaeologists recovered over 2,000 artifacts related to shipbuilding and machinery repair. The material culture record was supplemented by a plat showing wharf lot titles, a floating dry dock, and two useful plans dating respectively to 1879 and 1891 showing landscape features like a fence, engine house, power plant, railway, and city saw mill, and docking area (Babits and Barnes 1984: 48–52). The site was increasingly critical to regional shipping and tracing the sales of this property through time reflected a shift in the use of the harbor and shipyard from small, locally owned companies to a large corporate structure with greater fiscal stability and ability to monopolize the shipping industry.

During the latter half of the eighteenth century, Hobcaw Creek outside Charleston became the colony's largest shipbuilding center despite the presence of smaller yards scattered around the colony. An advertisement in the *South Carolina Gazette* on November 30, 1769 by these new partners lists the services of Hobcaw yard and John Rose's other yard, Rose's Wharf in Charleston, including shipbuilding, heaving down, repairing, graving, and mast building. Apart from their service as a shipbuilding depot, the yard also represented a sales depot that supplied the products required for shipbuilding and repair like live oak, cypress, and spars for topmasts, yards, and booms. Despite the existence of several yards on Hobcaw Creek, the success of the yard was attributed to attractiveness of this specific location for naval shipbuilding, sufficient space to heave down three large vessels simultaneously, good depth of water, a freshwater spring close to the shore, and enough distance away from the distractions of the city of Charleston to the laborers. From formative status as a plantation smallholding to small private yard run by two

shipwrights, it evolved into the largest state yard leased by the South Carolina Navy during the Revolutionary War. Ultimately, the successful shipyard reverted back to a smallholding in the aftermath of the war, and the shipwright, John Rose, left for Jamaica where he used his shipyard earnings to purchase over 9,000 acres and 221 slaves (Harris 2010: 17–35).

Clients of shipyards also reveal why one shipyard succeeded economically over another – reputable craftsmen, timely completions of tasks, and use of high-quality lumber. Loss of labor, including slave labor, resulted in losing the edge with competing shipyards. Sufficient resources to purchase and train shipyard slaves was more beneficial to business than renting slaves from planters. Consensus between business partners in shipyard businesses about investments and business practices was also a critical part of the equation, as demonstrated in the case of Hobcaw where squabbles about managing shipyard finances ultimately led to a suicide, or murder, of one of the shipyard partners.

By the mid- to late 1800s through years of the Civil War and postbellum period, concerns about the wartime vulnerability of shipyards on the coast and the convenience of shipping hardware materials and machinery by rail became critical planning factors in shipyard location. Southern shipyards served as manufacturing facilities and needed convenient access to transportation networks, building materials, and labor. Other considerations for fiscal success in the investigation of Mars Bluff Confederate War shipyard was proximity of clientele for shipbuilding and repair contracts and a wealthy community to raise funds and invest in the shipyard operation when warfare drained government subsidy of wartime manufacturing.

Shipyard studies primarily consider the role of European men. Less evident are the significant background roles played by women and slaves from the surrounding community in supporting the success of this southern manufacturing industry. Similar to plantations a skilled workforce comprised of slave artisans were an important ingredient for success. Women also played a role in the financing and support behind shipyards, whether through marriage and connections to the local community. Others participated in fundraising and attracting men to the shipyards with social events (Harris 2010: 34–35).

In 12wAustralia, ship graveyards or discard areas are frequently also the locale of repairing, modifying, and building ships from recycled parts. In Tasmania ship repairers used the waterway as a demolition yard for vessels beyond repair with floatation problems. Major shipbuilding locations along the Derwent River were situated close to ship dumping grounds (Richards 2008: 88–89). Other places in the world also have correlates between dismantling of ship timbers and shipyards, for example, Egypt, and waterfronts like Dublin in Ireland, Bergen in Norway, and numerous English port cities (Richards 2008: 26). The recycled parts are, in essence, potential chronological records and signatures of socioeconomic trends linked to the life of the shipyard in proximity. A 1,800 shipbreaking yard in San Francisco, California, represents the deliberate salvage of unused hulks along the waterfront subsequent to the Gold Rush (Pastron and Delgado 1991).

Future Directions

Possible directions for future research include delving deeper into the historical fabric, ethnographic record, and social narrative from actively working shipyards around the world to develop new frameworks and research questions of a more global character. Neglected geographic areas of scholarship, beyond Europe and North America, suited to shipyard research might be explored to assess potential for contributions to shipyard archaeology and history, for example, sites of traditional dhow shipbuilding at East African Swahili ports (Figs. 3 and 4), along the coast of the Persian Gulf at centers like Qesh, Khamir, Kong, Busher, Ganaveh, Chabahar, and Jask (Fig. 5) (Agius 2008: 142–147; De Leeuwe 2005: 107–113), and in India at Surat, Gujarat, and Alang.

Archaeologists might consider looking beyond seventeenth- to nineteenth-century shipyards to

Shipyard Archaeology, Fig. 3 Boatbuilding in Tanzania (Courtesy of Lynn Harris)

Shipyard Archaeology, Fig. 4 Maintenance on a Tanzanian dhow at low tide (Courtesy of Lynn Harris)

investigate the potential of derelict twentieth century, World War I and II shipyards drawing on a wealth of literature. Historical publications present vibrant and colorful compilations of personal anecdotes and historical information from letters and legal documents. Photographs depicting shipyard facilities, workers, and working scenes add to the appeal of historical investigation and could serve as an essential supplement to material culture studies of shipyards.

Another key direction is exploring appropriate archaeological methodology to interpret

Shipyard Archaeology, Fig. 5 Shipyard in Iran (Courtesy of Sorna Khakzad)

shipyard sites and make meaningful contributions to the historical record and management inventory. Ford (2006) and Moser (2011) attempted to create models and typologies using landscape features combined with the historic record to create layers in geographic information systems to predict, locate, and identify shipyard sites in Maryland, USA. While this study contributed to the archaeological and historical database in the state, an acknowledged limitation was that the footprint of substantive archaeological remains was very ephemeral due to shoreline filling, erosion, and development. Artifacts were not specific to shipbuilding and it was impossible to incontrovertibly conclude the presence of a shipyard. These two studies are landmark works towards the archaeological inventory and interpretation of shipyard sites in the new millennium that might be duplicated in other areas of the world.

Beyond basic inventory and exploring reasoning in selecting shipyard location, a productive example of a shipyard study is Goodburn's (1999) investigation of postmedieval London waterfront where researchers correlated tool marks on wood recovered from shipyards to tools and practices of shipwrights through time. Other diagnostic features of prominence at shipyards are remnants of wharves and docks. There is growing body of unpublished theses and dissertation scholarship since the 1980s on these structures in other contexts, like plantations and waterfront settlements that include critical assessments of typologies, recording methodologies, and theoretical frameworks that might be fruitfully applied to shipyard research. Most recently, a new and less static direction of study by Blackman (2011) that might be duplicated as an analytical framework is the query into the sociology of landings in the Baltic Sea Region that reaches across time and space, considering shifts in social relations and site functions.

Shizitan

Yanhua Song
History and Culture College, Shanxi University, Taiyuan, China

Introduction and Definition

The **Shizitan site** is an open-air archaeological site located along the Qingshui River, a perennial tributary of the Yellow River, Jixian County, Shanxi Province, North China. It includes several dozen identified localities, of which S1 (Linfen Administrative Bureau of Culture 1989), S5 (Shizitan Archaeological Team 2016), S9 (Song 2012), S12 (Zhao 2008), S14 (Shizitan Archaeological Team 2013), and S29 (School of History and Culture, Shanxi University & Shanxi Provincial Institute of Archaeology 2017) have been excavated (Fig. 1). The site was first excavated in 1980 and was interpreted as a "Mesolithic" site (Linfen Administrative Bureau of Culture 1989). Subsequent field work was conducted from 2000 to 2010 and showed that the site mainly contains Late Upper Paleolithic (LUP) deposits (Fig. 2). The excavations have yielded important new information on the chronology and environmental background for the evolution of Paleolithic lithic and bone tool

Shizitan, Fig. 1 The geographical position of S29, S9, and other excavated Paleolithic localities along the Qingshui River, Jixian County, Shanxi Province

Shizitan, Fig. 2 The stratigraphic section and cultural layers at Shizitan 29

technology, exploitation of plant foods, diffusion of modern human in East Asia, and adaptations to Ice Age conditions.

Systematic radiocarbon dates show the Shizitan localities date between c. 28,500 and 18,000 years, and c. 14,000–13,000 years before present (BP). The earlier deposits are mainly represented by S29, which features deposits up to 15 m in depth reflecting changing environmental conditions, as seen through water and wind deposition, as well as the activities of animals and humans (School of History and Culture, Shanxi University & Shanxi Provincial Institute of Archaeology 2017; Song et al. 2017). Later deposits are represented by S9, with 5 m-thick deposits that include the cold period of the Younger Dryas (Song 2012; Liu et al. 2011).

Key Issues and Current Debates

The Site of S29

S29 (36°2′54″N, 110°35′22″E, 723 m above sea level) is located about 500 m east of Shizihe Village of Jixian County. It was excavated from March 2009 to October 2010 due to highway construction. The 1200 m^2 excavation area features a 15 m deep depositional sequence with 8 cultural layers (Level 8 is the lowers) with sterile geological layers between most of them. The excavation procedure used 1 × 1 m squares divided into quadrants and vertical spits of 10 cm to maintain spatial control. Locations of lithics and other cultural materials were recorded during excavation, and smaller artifacts were also recovered through dry and wet screening. More than 80,000 artifacts were recovered, including lithic artifacts (microblades and microcores), animal bones from at least seven kinds of big and middle-sized herbivores, grinding slabs and handstones, ochre pigments, and ornaments made of shells and ostrich eggshell (Fig. 3) (Song and Shi 2013; Song 2013). A total of 285 excavated hearths were found in Layers 1 through 7.

Analyses at the site of S29 include systematic series radiocarbon dating, pollen and non-pollen palynomorph studies, zooarchaeology, and soil micromorphology (Song et al. 2017). These allow a detailed understanding of the chronology, formation processes, and changing environment of the site. Layer 8 (ca. 28 Ka cal BP) dates before the Last Glacial Maximum (LGM) and shows a warmer and damper climate. Layer 7 (ca. 26–24 Ka cal BP) reflects colder conditions setting in at the beginning of LGM. Full cool and dry conditions of the LGM continue during Layers 6–3 (ca. 24–19.5 Ka cal BP), and Layer 2 (ca. 19–18 Ka cal BP) marks the end of LGM conditions. Thick geological deposits during the occupational gap above Layer 2 show warming conditions, and human occupation begins in Layer 1 ca. 13 Ka cal BP. The LGM sequence at the S29 and the northerly location of Shizitan during LGM makes the site central to debates on how humans adapted to local conditions during the LGM: the site shows that some human groups were able to live this at this latitude rather than needing to migrate to warmer conditions in the south.

The site of S29 revealed some of the important adaptations made by hunter-gatherers to LGM conditions. First is the use of fire. Clear outlines of hearths first appear in Layer 7. A total of 285 such hearths were excavated, with 278 (98%) coming from LGM layers. Firewood could be identified as coming from pine and several other coniferous tree types based on identifications to the genus level on tracheal cells of wood in NPP samples. There is also indirect evidence at S29 for the humans making clothing. Detailed studies on the eyed bone needles from the site show that they were used for sewing at the onset of the LGM (Song et al. 2016). Although further studies are needed, the NPP samples also show potential evidence for the processing of flax fibers and the use of wool and bird feathers. Nine species of wild flax grow in central and northern China and could have been used long before domestication (Song et al. 2017).

Shizitan, Fig. 3 The perforated ornaments from S9 and S29. (**a**) Ostrich eggshell ornaments (S9: L4); (**b**) shell ornaments (S9: L4); (**c**) ostrich eggshell ornaments (S29: L7); (**d**) shell ornaments (S29: L7)

The cultural layers at S29 also supply diachronic evidence for a key change in Upper Paleolithic lithic technology, with the earliest well-dated appearance of microblade production. Layer 8 features a "core and flake" industry (recently also referred to as "flake and shatter"), but a dramatic change occurs at the top of Layer 7 with the appearance of microblades and microcores along with such new types of stone tools as end-scrapers and burins (Fig. 4). A techno-functional study of lithic production and raw materials (local black flint and pebbles from the Yellow River) supports ideas that these new technologies may be derived from hunter-gatherer groups who lived further north, so microblade technology was introduced into the North China Loess Plateau rather than being invented there (Song et al. 2019).

Grinding slabs and handstones at Shizitan localities and other Upper Paleolithic sites are a unique feature of this time period in China. Macroscopic use wear and starch residue analysis on the surfaces of grinding stones made of sandstone and other chipped tools made of flint or quartzite uncovered in Layers 8, 7, 4, and 2 at S29 show that plant food was processed on site. Poaceae phytoliths, which are also an indicator of anthropogenic changes in soils, are present as well. Wild Poaceae was important in the human diet of the Upper Paleolithic, and microremains of these plants (pollen, phytoliths, starch, stems, epidermis) were observed in all the cultural layers. Looking at the whole of the data, even though certain details are missing, during the LGM, the Shizitan hunter-gatherer groups likely exploited a broad spectrum of food resources. Various cereal

Shizitan, Fig. 4 The stone artifacts at S29. (**a**) Scraper (L8); (**b**–**d**) microblades (L7); (**e**–**f**) semi-conical microcores (L7); (**g**–**h**) boat-shaped microcores (L1; L6–7); (**i**–**j**) retouched blade (L7); (**k**) blade-blanked burin (L7); (**l**–**m**) bifacial points (L3; L1)

plants, as well, were harvested and processed as early as the LGM. This may be indications of the initial step that eventually leads to millet production in North China but is also some 18,000–14,000 years before the earliest evidence for domesticated millet in this region (Liu et al. 2018).

The Site of S9

Shizitan Locality S9 (36°2′11″N, 110°32′40″E, 688 m above sea level) provides evidence for the transition from the Late Upper Paleolithic to early Neolithic periods. It is located about 150 m north of Gaolouhe Village of Jixian County. The site was identified in 2000 and excavated over three seasons in 2001, 2002, and 2005. The excavated area reached 25 m^2 with deposits 455 cm in depth primarily feature aeolian loess sediments. These can be divided into five cultural layers, for which 9 AMS ^{14}C dates are available. A total of 2,359 screened artifacts and an additional 5,000 sieved pieces, primarily lithic artifacts and animal bones, along with occasional grinding stones (Fig. 5), pigments, and ornaments, were recovered from all layers except Layer 2. Fire use is indicated by a hearth in Layer 3 but was in general use, as seen through most animal bones being broken and burnt. The most informative finds are grinding stones, pigments, and ornaments made of shells and ostrich eggshell (Fig. 3) (Song et al. 2011; Song 2013; Song and Shi 2013) found only in Layer 4.

Shizitan, Fig. 5 The grinding stones excavated from S9

Ongoing research shows that the lowest layer, Layer 5 (ca.13.8–13 Ka cal BP), features a warmer and damper period immediately followed by Layer 4, which dates ca.12.8–11.4 Ka cal BP, during the Younger Dryas (YD) period (a period of sudden climatic worsening and return to glacial conditions in the northern hemisphere dating 12.8–11.5 Ka cal BP). This is one of the few sites in North China for which we have YD data. The end of the YD marks the beginning of the Holocene and warmer conditions, during which there was a short break in the occupation of S9 seen through the sterile deposit between Layer 4 and Layer 3 (ca. 9.5–8.4 Ka cal BP). During the time period of Layer 3, a profound change in human behavior occurs with the appearance of millet-cultivating Neolithic villages in lowland North China, but these farming populations have not yet spread into the Loess Plateau, where we still see hunter-gatherers who will soon need to adapt to encroaching farming populations.

Shizitan grinding stones provide evidence for the early use of these objects in food processing in North China. The grinding stones that date to the YD generate important insights into the origin of millet exploitation and the transition from the Late Paleolithic to early Neolithic period. The residue and use-wear analyses of the S9 grinding stones shows that they had multiple functions including wild plant processing, grinding pigments, and shaping materials that were used in ornaments (so possible for making the ornaments). An increase through time is seen in the proportion of the grass subfamily Panicoideae identified in the starch grain samples, indicating an intensification in the use of wild serials occurring at S9 through time. People here may also have become more semi-sedentary, as evidenced by the grinding stones and cereal exploitation, perhaps. The site of S9 can be seen as representing an early-stage cereal exploitation, with a new, intensive gathering of wild cereals before the intentional initiation of millet cultivation in North China (Liu et al. 2011; Song et al. 2013).

Future Directions

Based on more than 10 years' field work, Shizitan site owns her potential to be well known by international archaeologists by broadening the international co-operations and multidisciplinary approaches. More detailed researches on the diachronic changes of Paleolithic technology and the selective use of high-quality raw materials are ongoing. New lines of research are also focusing on the structural and functional changes of hearths. The relative results will shed light on the cultural diversity of modern human and the cultural exchanges among human populations in larger geographic areas beyond the Middle Yellow River.

Siberia: Paleolithic

Jiri Chlachula
Laboratory for Paleoecology, T. Bata University in Zlin, Zlin, Czech Republic
Institute of Geoecology and Geoinformation, Adam Mickiewicz University, Poznan, Poland

Introduction

Siberia is a territory of 13.1 mil km^2 encompassing the northern part of Asia east of the Ural Mountains to the Pacific coast (the Far East). This vast area has major significance for documenting the evolutionary processes of initial human settlement in the frame of past climates and climate change in the boreal and (circum-) polar regions of the Northern Hemisphere. Particularly, the central continental areas in the transitional subarctic zone between the northern Siberian lowlands south of the Arctic Ocean and the southern Siberian mountain systems characterized by a strongly continental climate regime have been subjected to multidisciplinary Quaternary (paleoecological and geoarchaeological) investigations during the last decades. Siberia is also the principal territory for transcontinental studies and correlations of geological climate proxy records across Eurasia following the East-West and South-North geographic transects (Fig. 1). Among them, loess (fine aeolian dust) represents, together with the Lake Baikal limnological archives, the most significant source of globally indicative paleoclimate and paleoenvironmental data with bearing for reconstruction of the past climate history in the north-central Asia (Chlachula 2003a).

The broader Siberia with the adjacent parts of the Urals and the Russian Far East (the Primorye, Magadan and Chukotka regions) has the key

relevance for elucidation of timing and conditions of environmental adaptation of the prehistoric and early historic people to the high latitudes of Eurasia, as well as the initial colonization of the Pleistocene Beringia, including the NW of the American continent. The particular geographic location and the variety in topographic configuration of regional landscape reliefs together with changing Quaternary environments governed by the past global climate change played the key role in this long and complex process over the last 2.4 Ma. The spatial and contextual distribution of the documented archaeological sites reflects a climatic instability and a timely discontinuous inhabitability of particular geographical areas of Siberia. The cyclic nature of glacial and interglacial stages led to periodic geomorphic transformations and generation of specific ecosystems adjusted to particular topographic settings and responding to acting atmospheric variations. Diversity of the present reliefs and environments, reflecting the past climate change, played the key role in the process of the initial peopling of the immense territory. Paleoenvironmental databases (palynological, paleontological) as well as early cultural records provide unique evidence of strongly fluctuating Pleistocene glacial and interglacial climates, corroborating the continental geological as well as Marine Oxygen Isotope (MIS) chronostratigraphic archives. Because of the large spatial extent and a limited accessibility, particularly the north(eastern) regions of Siberia and the Russian Far East belong to the least explored ones in terms of elucidating the World prehistory.

Definition

The regional geographic diversity with vegetation zonality of Siberia encompassing the southern parkland steppes and semi-deserts, vast boreal taiga forests, and the northern Arctic tundra illustrates the diversity of the present as well as past environments, with the most extreme seasonal temperature deviations in the World ranging from +45 °C to −80 °C. The main physiographical units include the continental basins of the Western Siberian Lowland, the Lena and Kolyma Basin; the southern depressions (the Kuznetsk, Minusinsk, Irkutsk and Trans-Baikal Basins); the Central Siberian Plateau; and the mountain ranges in the South (Altai, Sayan, Baikal, and Yablonovyy Range) and in the North-East Siberia (Stavonoy, Verkhoyanskyy, Suntar-Hajata, Cherskego, Kolymskyy Range). The major Siberian rivers (Ob, Yenisei, Lena, Kolyma) drain the territory into the Arctic Ocean. The Cenozoic neotectonic activity together with the periodic Pleistocene glaciations and interglacial geomorphic processes modeled the configuration of the former relief. During the cold Pleistocene stages, the vast extra-glacial regions of West Siberia south of the NW Arctic ice-sheet were transformed into a large periglacial superzone which became a major sedimentation area of aeolian (silty) deposits cyclically derived by winds from the continental ice-front ablation surfaces. Main paleoenvironmental records, spanning over several hundred thousand years, have been preserved in deeply stratified sections within the major basins (Ob, Yenisei, Angara, and Lena River) that were exposed after progressive erosion triggered by constructions of large dams. Equally important sources of the Quaternary (geological and biotic) paleoclimate proxy data originate from open-coalmines and other modern industrial landscape disturbances.

Because of the complex, multifactorial nature of a long-term climatic and ecology evolution, Siberian geoarchaeology-oriented studies have become increasingly interdisciplinary, integrating Quaternary geology and paleogeography, paleopedology, paleontology, paleobotany, Paleolithic archaeology, and other fields (Chlachula et al. 1999, 2014; Prokopenko et al. 2001; Derevianko et al. 2005; Chlachula and Catto 2010; Ineshin and Teten'kin 2017). Reconstructions of past environments in the specific regions and the time periods have been used to assess the effects of orbital variations on seasonal and latitudinal distribution of solar radiation and atmospheric circulation patterns and the consequential changes in regional temperatures, precipitation, and moisture balance. Some long-term models provide means of predicting future climatic evolution in the context of the global climate history and help in the assessment of the modern human

factor in environmental change. Because of the pronounced climatic continentality of the territory, even minor variations in atmospheric humidity and temperature led to major transformations in local ecosystems, particularly in the open southern Siberian continental sedimentary basins and the upland depressions.

Geoarchaeology of the Siberian Paleolithic and Mesolithic, framed into the broader scope of Quaternary science, chronologically entails the Pleistocene time span with the documented cultural records dating from the Early till Final Pleistocene depending on the particular geographic area (Chlachula 2017). The evidence of the occupation includes technologically diverse stone and bone industries, butchered fossil fauna remains, paleoanthropological remains, fireplaces, and other early human behavioral elements stored in geo-contexts.

Historical Background

Until the 1980s, Siberia was generally believed to have been colonized by the Late Pleistocene people. Human occupation was traditionally associated with the Late Paleolithic cultures (Tseitlin 1979). Systematic geoarchaeology investigations during the last 20 years across the entire Siberia (with the key research loci in the Tran-Ural region of West Siberia, the Altai region, the Upper Yenisei, Angara and Lena Basins, as well as at the easternmost margins of the Russian Far East in Primoriye and on the Sakhalin Island) revealed several hundred of Paleolithic and Mesolithic sites (e.g., Astakhov 1986; Derevianko 1990; Drozdov et al. 1990; Larichev et al. 1990; Medvedev et al. 1990; Mochanov 1992; Derevianko and Markin 1992; Konstantinov 1994; Markin 1996; Chlachula et al. 1999, 2003; Mochanov and Fedoseeva 2001, 2002; Zenin 2002; Vasilevskyy 2008; Derevianko and Shunkov 2009). Particularly the discoveries of numerous Paleolithic locations, some of potentially great antiquity (>0.5 Ma), in large-scale surface exposures (river erosions and industrial mining) followed by systematic archaeological investigations within the major river basins of south and central Siberia between the Irtysh River in the west and the Lena River/Lake Baikal in the east (Fig. 1), have provided overwhelming evidence of a much greater antiquity of human presence in the broader Siberia and capability of early people to adjust to changing Pleistocene environments. Cultural remains are located in diverse geomorphic settings (i.e., lowland plains, mountain valleys, upland plateaus) and geological contexts (aeolian, fluvial, lacustrine, palustrine, alluvial, glacial, and karstic), with the highest concentrations in the Pleistocene periglacial parkland steppe and the boreal tundra-forest foothill zone. Particularly the geographically extensive and deeply stratified loess-paleosol sections in the southern Siberian parkland zone have revealed a long and complex cultural sequence of human occupation. The variety of cultural finds provides witness to several principal stages of inhabitation of the Pleistocene Siberia, possibly encompassing the time interval close to 1 Ma. The earliest (Early/Middle Pleistocene stages) are represented by "pebble tool" industries, followed by the Middle Paleolithic complexes, including the (Neanderthal) traditions with the Levallois prepared-core stone-flaking technology, and the regionally diverse Late/Final Paleolithic blade complexes eventually replaced by the microlithic Mesolithic cultural facies that developed in response to major natural transformations during the final Pleistocene.

A further northern geographic expansion of humans into the Arctic regions reflects a progressive cultural adaptation to extreme climatic conditions of (sub)polar Pleistocene environments (Mochanov and Fedoseeva 2002). Presence of the Paleolithic sites in North Siberia (Pitulko et al. 2004) provides eloquent evidence that people reached the Arctic coast already before the Last Glacial (>24,000 years ago/24 ka BP). All these discoveries logically lead to revision of the traditional perceptions on a late peopling of northern Asia as well as the "late chronology" models of the initial human migrations across the exposed land-bridge of Beringia to the North American continent (Chlachula 2003b). Geoarchaeology studies, particularly in the poorly explored and marginal geographic regions of northern and

eastern Siberia (Slobodin 1999; Vasilevskyy 2008), are of utmost importance for reconstruction of past climate change as well as the early human history in north Eurasia.

Key Issues/Current Debates

Siberia has principal bearing for elucidating the prehistory of peopling of northern Eurasia, with the key issues of the traditional debate – the antiquity, the chronology of migration processes, and the environmental contexts of the Pleistocene dispersal of early humans within this vast territory. A specific study issue is the cultural adaptation in the extreme environments of the Russian (sub-) Arctic regions. Interactions of past climate change and the regional relief modeling triggered by the neotectonic activity and reflected by natural transformations of local ecosystems attest to the complexity of the Quaternary landscape development, ultimately affecting timing, intensity, and adaptations of the early human occupation of north-central Asia. Contextual geology, paleoecology, and paleontology records from investigated archaeological sites and stratified geological sections provide evidence of pronounced (paleo) environmental and biotic shifts triggered by the global climate evolution as well as the associated glacial and interglacial geomorphic processes. Quaternary climatic cycles regulated spatial and temporal movements of prehistoric people into the high latitudes of Eurasia. Integrated ecology multiproxy databases thus document trajectories of the complex and long occupation history of this extensive, but still rather marginally known part of the World.

Southwest Siberia

Natural Context, Paleogeography, and Climate History

The territory of West and SW Siberia, encompassing the West Siberian Lowland, the Altai region, and the Kuznetsk Basin, is characterized by a mosaic physiography with high mountain massifs in the south and east (max. 4,506 m asl), and open lowlands in the north and west (Fig. 1). Hydrologically, the area belongs to the Ob River drainage system with the Katun', Biya, Irtysh, and Tom' River being the main tributaries. The lower relief zone (>1,200 m asl.) includes >50% of the area and constitutes relics of old denudation surfaces covered by more recent (Pleistocene) deposits derived during glaciations. The territory shows a complex Quaternary history for the last 2.5 Ma governed by climate changes leading to the present pronounced continentality of the inner Eurasia in association with a regional Cenozoic orogenic activity initiated by the Miocene uplift of the Trans-Baikal region and reaching the Sayan-Altai area during the late Pliocene (3 Ma ago). Dynamics of these processes continued until the early Middle Pleistocene leading to construction of a system of mountain ranges separated by deep depressions filled by lakes. The beginning of the Pleistocene period brought a major modification of former landscapes as a result of dramatic climatic changes with progressive continental cooling and aridity. Periodic glaciations caused a regional topographic restructuring with intensive erosion in the glaciated zone and accumulation of (pro)glacial, alluvial, proluvial, lacustrine, and aeolian deposits in the intramontane depressions. The geological records display a wide range of environments and climates. Particularly the deeply stratified loess-paleosol sections deliver most detailed information on high-resolution and globally indicative Late Quaternary atmospheric variations in Siberia.

The climate evolution in the southern mountain regions is witnessed by interglacial alluvial deposits separated by glacial moraine (till) formations with the most extensive dating to the final Middle Pleistocene (MIS 6) glacial stage. The alpine glaciers periodically formed coalescent ice fields supporting large glacial lakes in the central and southern mountain basins of Gorno Altai followed by cataclysmic drainages shaping the paleolandscape topography in the form of prominent glacio-fluvial terraces (Fig. 2). The two Late Pleistocene glacial stages (MIS 4 and 2) are separated by the mid-Last Glacial (MIS 3) warming (59–24 ka BP) associated with accumulation of gravelly alluvial sediment facies from the

Siberia: Paleolithic, Fig. 2 A system of terraces at the confluence of the Katun' and Chuya River (Gorno Altai) resulting from cataclysmic drainages of ice-dammed glacial lakes. The mountain areas of Siberia provide witness of major past geomorphic processes having impact on visibility and preservation of the Pleistocene occupation sites

former ice ablation. The broken mountain relief differentiated the regional climatic pattern during the Last Glacial (24–12 ka BP), with microclimate conditions in protected locations along the northern Altai foothills and in the central Katun' River basin, allowing potential survival of interstadial flora and biota until the Holocene. The Pleistocene climate variations in the lowland extraglacial areas of SW Siberia and the continental depressions north of the Altai-West Sayan Mountains are evidenced by a massive deposition of aeolian (silty and sandy) deposits during glacial periods and surface stabilization with soil formation during warm (interglacial/interstadial) stages. The extensive loess-paleosol formations on the Altai Plains provide the most detailed multiproxy records of the climatic cycles for the last c. 300,000 years. The MAT during the Last Interglacial climatic optimum (MIS 5e, 125 ka BP) in SW Siberia was by 1–3 °C higher than at present, with a c. 100 mm increase in annual precipitation. Environmental conditions were broadly similar to the present ones during the following interstadials that were the most suitable time intervals for human colonization and inhabitation.

Pleistocene Environments and Early Human Occupation

Studies of the Paleolithic and Mesolithic occupation have a long tradition in Siberia with the key foci in the Altai region. The transient geographic areas along the margin of SW Siberia are believed to be the main gateway and passages for early human migrations from the southern regions of Central Asia into Siberia (Fig. 1). Reconstruction of the past climate dynamics that shaped the configuration of the regional topography and local ecosystems is essential for understanding timing and adaptations of the initial peopling of northern Asia. The spatial distribution of the Pleistocene sites on the territory of SW Siberia shows a location of most sites within the 75–150 km wide zone of the 300–1,000 m altitude between the southern mountain ranges and the northern plains and

lowlands (Baryshnikov and Maloletko 1999). This (paleo)geographic occupation pattern, reflecting specific environmental adaptation strategies to local settings, applies for both open-air localities buried in alluvial, colluvial, or aeolian deposits, as well as cave sites concentrated in the NW Altai (the Anui valley). Formation of the karstic systems is linked to a progressive downcutting by fluvial erosion through the Devonian-Carboniferous limestone bedrock during the late Middle Pleistocene.

Timing of the Pleistocene human migrations in Siberia was principally governed by climatic change and the associated environmental development. Intensified orogenic uplifts, triggering large-scale erosions in river valleys, reshaped natural occupation habitats. Relatively stable conditions seem to have persisted in the central and northern Altai due to increased regional precipitation and a tempering atmospheric effect of the mountain ranges. Limestone caves provided shelters for a more permanent human inhabitation of the Altai area, particularly in the northern foothills and the central intramontane depressions (Derevianko and Markin 1992; Markin 1996), characterized by warm microclimate conditions. The initial peopling of the Altai-West Sayan region likely occurred in some of the early Middle Pleistocene interglacials in the process of the northern expansion of warm biotic communities. Mixed coniferous and broadleaf forests established in the mountain areas with elevations 1,500–2,000 m asl. Parklands covered most of the adjacent plains of southwest Siberia with continental depressions filled by lakes and drained by meandering rivers. Rudimentary core and flake ("pebble tool") stone industries scattered on high river terraces and along former lakeshore margins of the present arid basins (Kuznetsk and Zaisan Basin) attest to several stages of early human inhabitation and a relative environmental stability (Chlachula 2010). There is limited evidence on persistence of the Early Paleolithic occupation during glacial stages, although some intermittent semi-continuity in the southernmost areas is assumed in view to finds of weathered lithic artifacts from the old periglacial alluvia in association with cold-adapted megafauna. Mastering the technique of fire making was clearly the main precondition for early human survival in cold tundra-steppe and tundra-forest habitats of southern Siberia.

The Last Interglacial warming (starting at 130 ka BP) is associated with a recolonization of southern Siberia by coniferous taiga forests and the appearance of the Mousterian Neanderthal tradition. Changes in the relief configuration influenced a regional climate regime and opened new niches of habitats for the Middle Paleolithic population concentrated in the karstic area of the NW Altai foothills (Ust'-Kanskaya, Strashnaya, Denisova, Okladnikova, Kaminnaya Caves) as well as at open-air sites in the central valleys (Kara-Bom, Ust'-Karakol, Tyumechin I and II) (Derevianko and Markin 1992; Chlachula et al. 1999; Derevianko et al. 2005). The Middle Paleolithic horizons, encompassing a timespan of up to 140,000 years (180–40 ka BP), represent a marked cultural phenomenon in the Altai (Figs. 3 and 4). Isolated teeth (2) from the Denisova Cave dated to MIS 5 and identified as *Homo neaderthalensis* support the model of biological evolution of premodern humans in Siberia (Derevianko and Shunkov 2009). Major cooling during the early Last Glacial (MIS 4) led to establishment of full glacial conditions in the central and southern Altai, and a zonal geographic replacement of boreal forest by periglacial tundra forest in the northern Altai and by arid tundra-steppe in the adjacent lowlands (the Ob River basin and the Kuznetsk Basin). Accentuated moderate climate fluctuations between cold stadials are evidenced by embryonic regosolic soils in the loess formations on the North Altai Plains and sparse cultural records in protected locations in the Altai foothills.

Human occupation of the central and southern Altai during the early Last Glacial (74–60 ka BP) was impeded by harsh, ice-marginal environments and expansion of glaciers in the upper reaches of the Katun'-Chuya valleys subsequently filled by proglacial lakes. Progressive warming during the early mid-Last Glacial interstadial interval (MIS 3, 59–35 ka BP) caused a dramatic wasting of the ice fields accompanied by cataclysmic releases of ice-dammed lakes and large-scale

Siberia: Paleolithic, Fig. 3 Stratigraphy of the multi-layer Denisova Cave Site (the Anui River valley, NW Altai) enclosing a series of c. 15 occupation horizons dating since the late Middle Pleistocene until Holocene

mass-flow and slope erosional processes (Fig. 2). The former valley glaciers receded to the highest elevations as corrie glaciers. The periodic outbursts of the glacial basins had a dramatic impact on the local ecosystems, but also obliterating most of the earlier cultural records. Enormous erosional processes associated with these major events significantly reduced the site visibility potential in the formerly flooded areas, with traces of former inhabitation locations preserved only at high topographic elevations above the glacial lake basin waterlines (Fig. 5). Mixed forests dominated by birch, pine, spruce, and fir invaded the former periglacial and ice-marginal landscape. The presence of broadleaf arboreal taxa (oak, lime, chestnut, maple) indicates a climate warmer than at the present time.

Increased humidity and cooling during the later stage of the mid-Last Glacial interstadial interval (35–24 ka BP) initiated mass gravity slope processes and cryogenic deformations followed by warmer oscillations with formation of podzolic gleysols (Fig. 6). Appearance of the transitional early Late Paleolithic cultural facies reflects human adaptation to mosaic interstadial habitats, including subalpine taiga, dark coniferous forests, mixed parklands, and steppes with mixed nonanalogue biotic communities. The identical geographical distribution of the Middle-Late Paleolithic sites and the time-transgressive lithic technologies suggests a regional cultural (and biological?) continuity in the Altai area during the Late Pleistocene (Derevianko 2010). A phalanx fragment from Denisova Cave dated to 40,000 years ago and interpreted on basis of DNA as an extinct human species (Dalton 2010) reinforces this scenario. Reestablishment of cold tundra-steppe habitats correlates with dispersal of the developed Late Paleolithic with blade-flaking techniques in stone tool production and associated with a periglacial "mammoth" megafauna that possibly survived in protected and climatically milder locations in the northern Altai throughout the LGM (20–18 ka BP). Emergence of the microlithic stone tool assemblages with wedge-shape cores is linked with a new cultural adjustment during the final stage of the Paleolithic development responding to natural transformations of the former periglacial ecosystems toward the end of Pleistocene.

South-Central Siberia

Natural Context, Paleogeography, and Climate History

The south-central Siberia, bordered by the western Mongolia from the South and the Central Siberian Plateau in the North, is topographically and biotically a varied territory structured by high ranges of the Sayan Mountains passing into foothills transected by river valleys draining water discharge from the southern mountain massive (Fig. 1). The regional (paleo)relief is built by the south Siberian continental basin with intermountain depressions modeled by fluvial erosion of the Yenisei River and its tributaries. An extensive loess cover with a series of buried

Siberia: Paleolithic, Fig. 5 Krasnaya Gorka Site (Gorno Altai). A view from the Paleolithic locality positioned on a promontory of an alluvial fan (1,780 m asl) over the Chuya River valley with stone artifacts made on high-quality raw materials (jasper, chert) exposed by erosion on the present top surface

Siberia: Paleolithic, Fig. 6 Stratigraphy of the Ust' Karakol Site (the Anui Halley, NW Altai) with several Late Paleolithic occupation horizons ^{14}C-dated to 28,700–31,400 year BP. Complex post-depositional processes are evidenced by slope-wash and cryogenic periglacial disturbances of the geological context due to climatic fluctuations in the Altai Mountains during the mid- and late Last Glacial stage

paleosols in the parkland-steppe zone of the Northern Minusinsk Basin, being a continuation of the southern Siberian loess belt, has provided the most complete, high-resolution Late Quaternary paleoclimate record in the north-central Eurasia (Chlachula 2003a). The interglacial periods are evidenced by stages of landscape stabilization and soil formation disrupted by intervals of loess deposition and cryogenic surface deformation during cold (glacial/stadial) stages. Coupled with the pollen evidence, the continuous loess-paleosol sequences encompassing a time interval of the last c. 300,000 years (MIS 8-1) document periglacial steppe-tundra established during cold stadials, replaced by mixed boreal forests and a mosaic parkland steppe during warm interstadials and interglacials. The associated Pleistocene natural transformations are reflected in the large diversity of fossil faunal species, including nonanalogue communities, to modern biota. The variety of the Quaternary faunal communities recorded in the Minusinsk and Kuzbas Basins documents particular evolutionary stages with zonal vegetation shifts triggered by pat climate change. The presence of cold-adapted species in the fossiliferous sedimentary beds indicates a very high biological potential of the Pleistocene periglacial steppe. A major drop of annual temperatures marks the time around the Last Glacial Maximum (20,000–18,000 years BP) that was less dramatic than during the preceding early Last Glacial stage (74,000–59,000 year BP). A progressive warming with several climatic oscillations expressed by an initial pedogenesis characterizes the Final Pleistocene climate development, leading to establishment of the Holocene (MIS 1) interglacial conditions. The present continental climate (with MAT −0.4 °C), with cold and dry winters with little snow cover and warm to hot summers, is strengthened by the geographical location of the territory near the geographical center of Asia.

Pleistocene Environments and Early Human Occupation

The upper Yenisei basin in the southern part of the Krasnoyarsk Region is together with the Altai

region and the Angara basin in the Irkutsk Region the key area of the Quaternary climate and Pleistocene geoarchaeology studies. Systematic investigations in the Northern and Southern Minusinsk Depressions, initiated after progressive erosion of unconsolidated aeolian (loess) deposits, revealed a rich series of Early, Middle, and Late Paleolithic stone industries associated with abundant fossil faunas (Drozdov et al. 1990; Chlachula et al. 1999). The main focus of the current studies is on reconstruction of the Pleistocene ecology and chronology of the human occupation in the frame of peopling of Siberia. The loess-paleosol formations, being the principal geological context of the early human cultural remains, also have a fundamental bearing for the high-resolution mapping of the past climate and the environmental history of north-central Asia. The archaeological and paleontological records incorporated in fluvial and subaerial sedimentary formations have provided new insights on timing, processes, and conditions of the initial peopling of this territory, as well as on the ecosystem biodiversity of the Pleistocene occupation habitats.

The earliest archaeological (Early Paleolithic) finds represented by simply flaked, but diagnostic stone artifacts originate, together with the taxonomically rich paleontological remains, from alluvial gravels of the 60–70-m Yenisei River terrace beneath 20–40-m thick loess deposits. The abundant "pebble tool" assemblages bear witness to human occupation of the area prior to the Last Interglacial (>130 ka BP). The formal variability of these lithic industries, displaying a differential degree of patination and aeolian abrasion, points to several stages of peopling with the earliest documented from the Tobol Interglacial (the Berezhekovo Site). The cultural implements also suggest, in conjunction with the cold-adapted megafauna, an early human adjustment to local periglacial environments. The archaeological records from the Minusinsk Basin, together with analogous finds from the Kuzbas and the Angara Basins (Medvedev et al. 1990), indicate a repeated occupation of the broader southern Siberia during the Middle Pleistocene (740–130 ka BP).

Evidence on the more recent Middle Paleolithic inhabitation of south-central Siberia is principally from the foothill areas of the Altai and Sayan Mountains and the local tributary river valleys (Konstantinov 1994; Derevianko 2010). Favorable climatic conditions promoted expansion of the Mousterian (Levallois) tradition during the Last Interglacial (MIS 5) that persisted until the early Last Glacial stage (MIS 4). In the Minusinsk Basins, the Middle Paleolithic is principally found in the Last Interglacial (130–74 ka BP) paleosols (Fig. 7). An exceptional Middle Paleolithic occupation site Ust'-Izhul' produced concentrated fossil skeletal remains incorporated in situ on top of the Last Interglacial (MIS 5e) chernozem IRSL dated to 125 ± 5 ka and overlying the 65 m Middle Pleistocene Yenisei terrace (Chlachula et al. 2003). The well-preserved fauna included an early form of mammoth (*Mammuthus primigenius* Blum.), wooly rhinoceros *(Coelodonta antiquitatis)*, bison *(Bison priscus)*, horse *(Equus mosbachensis)*, elk *(Cervus elaphus)*, as well as small mammals (Fig. 8). The most abundant species – mammoth – was represented by at least 12 individuals, parts of which were recorded in anatomical position. The associated and mostly expedient stone artifacts (200 pcs) were used for processing the slaughtered animals. Human activity is also manifested by flaked/cut ivory and bones of mammoth, rhinoceros, bison, and elk and by three fireplaces with a fir-wood charcoal ($^{14}C > 40$ ka BP). The paleogeographic site configuration with the discrete concentration of the skeletal remains points to game hunting by people in the nearby area over a terrace cliff and transported in dissected pieces to the habitation place. In respect to the high age and the contextual completeness, the Ust'-Izhul' locality is unique in Siberia. The megafaunal assemblages bear witness to the rich biological potential of the Yenisei area for early human inhabitation. There is no consensus if the Middle Paleolithic tradition in southern Siberia can be associated with the European and Near Eastern cultural milieu, although some "classical" Mousterian influences in the Altai cave sites are evident (Derevianko and Markin 1992). Analogous cultural finds are exposed on the present surface in low-sedimentation-rate areas of Khakhasia, Tuva, Gorno Altai, and East

Siberia: Paleolithic, Fig. 7 Late Quaternary loess sections at Kurtak exposed along the Krasnoyarsk Lake (the Northern Minusinsk Basin, south-central Siberia) with the Last Interglacial pedocomplex encompassing a time interval of 130–74 ka BP (Section Kurtak 29). The buried parkland-steppe paleosols (MIS 5e, 5c, 5a) correlate with stages of the Middle Paleolithic occupation of the area

Siberia: Paleolithic, Fig. 8 The Middle Paleolithic occupation site Ust'-Izhul' (the Kurtak Archaeological Region) dated to 125,000 year BP. Remains of megafauna (mainly of early *Mammuthus primigenius*) with stone artifacts and fireplaces attest to early human hunting and adaptation strategies in the upper Yenisei River Basin

Kazakhstan (Astakhov 1986; Chlachula 2010). The Middle Paleolithic stone-flaking technology, especially the Levallois technique, is still reminiscent in the Late Paleolithic traditions, suggesting a certain continuity of the cultural and possibly biological human evolution in Siberia during the Pleistocene.

The Late Paleolithic occupation in the southern Central Siberia is documented at both open-air and cave sites. Warming during the mid-Last Glacial interstadial stage (MIS 3) accelerated the cultural development characterized by blade-flaking techniques. The upper Yenisei basin is one of the major loci of the Late Paleolithic sites in Siberia (the Krasnoyarsk – Kanskaya forest-steppe, the Northern and Southern Minusinsk Basin, and the Western Sayan foothills) (Astakhov 1986; Drozdov et al. 1990; Larichev et al. 1990; Vasiliev 1992). The earliest occupations are buried in the Karginsk (MIS 3) pedocomplex (31–29 ka BP), in the early Sartan loess and the intercalated, weakly developed interstadial forest-tundra soils (dated to 25–22 ka BP). Intervals of significant climatic deterioration and onset of full Last Glacial (MIS 2) conditions are manifested by the absence of archaeological records except for biotic refugia in the northern foothills of the Western Sayans. During the LGM (20,000–18,000 year BP), the Yenisei area, as most of southern Siberia was vacated due to very cold and hyper-arid conditions with the biologically productive mid-Last Glacial parkland steppe replaced by barren steppe-tundra. More recent Final Paleolithic finds from the lowland and foothill areas provide evidence of recolonization of the upper Yenisei region during warm climatic oscillations at the end of the Pleistocene. A reindeer, red deer, argali sheep hunting, composite bone tools (spears/harpoons), and a microblade stone flaking illustrate major shifts in adaptation strategies in response to changing environments during the warm interstadial (16–13 ka BP), preceding the last cold climatic interval of the Final Pleistocene (Younger Dryas, 12.9 ka BP). The present archaeological records provide evidence that this territory was inhabited repeatedly at several stages during the Pleistocene, including some intervals of glacial stages with productive periglacial natural conditions. Human occupation may have persisted throughout the Last Glacial in protected southern locations despite severe climates over most of the northern plains.

East Siberia

Natural Context, Paleogeography, and Climate History

East Siberia, including the Pribaikal area (the upper Angara Basin), the Trans-Baikal area (the Selenga Basin), and the Lena Basin, is a vast territory of contact of the tectonic structures of the Siberian Platform and the adjoining mountain massifs (Fig. 1). The major orogenic activity initiated during the Pliocene/Pleistocene (the Baikal Tectonic Phase spanning for the last 3.5 Ma) led to formation of the present regional topographic configuration built by a series of tectonic depressions. The Baikal rift zone extends for about 2,500 km from Lake Khubsugul in Mongolia to the upper Aldan River in SE Yakutia. Most of the relief is shaped by smooth mountain ranges (800–1,300 m asl.) separated by river valleys and shallow basins occupied by mixed (spruce, larch, and birch) taiga forests. Cold and extreme continental climatic conditions prevail in East Siberia (MAT −4 °C). Most of the territory is covered by mountain tundra with larch *(Larix sibirica)*, Siberian pine *(Pinus sibirica)*, and dwarf birch *(Betula nana)* and underlain by seasonally active perennial permafrost.

The paleogeographical and paleoenvironmental evolution in East Siberia during the Quaternary was influenced by a dynamic interaction of global climatic change and the regional neotectonic modeling. The orogenic movement around the Pliocene/Pleistocene boundary (2.5 Ma ago) triggered uplifting of the Pribaikal and West Trans-Baikal regions, reactivated during the early Middle Pleistocene (after 750 ka BP) with accumulation of thick deltaic, fluvio-lacustrine, and slope deposits filling major river valleys and intermountain basins. The Cenozoic tectonics in conjunction with the mountain glaciations continuously shaped the topography of Eastern Siberia structured by a system of

mountain ranges (North Baikalskyy, Verkhoyanskyy, Cherskego, Kolymskyy) separated by the major (Angara, Lena, Viluy, Aldan, Indigirka, Yana, Kolyma) river basins and their tributaries. The subrifting regimes of the Mongolian-Siberian mountain zone gave rise to a diversity of geomorphic settings throughout the Pleistocene. Past glaciations in the East Siberian mountains, with the major one of the late Middle Pleistocene (MIS 8), played a significant role in the regional landscape development and environmental shifts in the extra-glacial depressions. Contrary to the Pribaikal Highlands, experiencing the most extensive glaciation during the Last Glacial Maximum (20–18 ka BP) with piedmont glaciers advancing far down into the foothills (Rezanov and Kalmikov 1999), only isolated ice-caps and corrie glaciers formed in the Eastern Sayan Mountains (above 2,700 m) and on the NE Siberian mountain ranges (Verkhoyanskyy, Cherskogo, Kolymskyy) despite very low temperature, but due to a high aridity and lack of winter precipitations.

The Pleistocene climatic variations in the extra-glacial areas are witnessed by a wide range of paleosols indicating mosaic vegetation and a high relief zonation. Increased accumulation rates of aeolian sediments with periglacial deformations point to a gradual cooling during the Late Quaternary. A major drop of temperature following the Last Interglacial climatic optimum (MIS 5e; 125 ka BP) around 115 ka BP (MIS 5d) suggests a major glaciation in the eastern Siberia corroborated by records from Lake Baikal as well loess-paleosol sequences (Prokopenko et al. 2001; Chlachula 2003a). The mid-Last Glacial (MIS 3) optimum (31 ka BP) was thermally approaching the Last Interglacial (MIS 5e) climate conditions. Fossil pollen, fauna, and early cultural records from stratified geological contexts including cryolithic permafrost formations of North Siberia (Fig. 9) provide evidence of structure and pronounced regional paleoecology changes in human occupation habitats. A greater variety of the early Quaternary faunal communities became reduced as a result of the long-term climatic cooling, leading to the relative taxonomic species uniformity in the Late Pleistocene.

Siberia: Paleolithic, Fig. 9 Anthropogenically worked quartz flakes from the Diring site from the 200 m Lena River terrace representing the earliest (Early Paleolithic) cultural inventories found in NE Siberia

Pleistocene Environments and Early Human Occupation

Present cultural evidence attests to several stages of human inhabitation of Eastern Siberia during the Pleistocene, with the oldest represented by the Early and Middle Pleistocene records, implying very early hominid migrations into the middle and high latitudes of Asia. Systematic investigations at the occupation sites in the upper Angara, Lena, Vitim, Aldan, Viluy, and Selenga River basins, along the Baikal Range and the Eastern Sayan foothills, contextually associated with diverse paleo-geomorphic zones and geological (alluvial, colluvial, aeolian, karstic) settings, deliver detailed multiproxy information on the Pleistocene climate evolution and the associated paleoenvironmental trends (Medvedev et al. 1990; Mochanov 1992; Konstantinov 1994; Lbova 1996; Mochanov and Fedoseeva 2002; Ineshin and Teten'kin 2017). Archaeological sites may be partly obliterated or poorly preserved around the Lake Baikal due to the neotectonic activity, triggering intensive erosional processes. The cultural finds, chronologically defined by the stratigraphic geological positions and technological attributes of stone flaking, include: (1) the Early Paleolithic from the Early(?)/Middle Pleistocene alluvial deposits (>130 ka BP); (2) the Middle Paleolithic buried in the Last Interglacial (MIS 5) pedocomplex and the early Last Glacial (MIS 4) gleysol horizons; (3) the early Late Paleolithic (42–30 ka BP) from the mid-Last Glacial (MIS 3) humic soils; (4) the "classical" Late

Paleolithic from the late mid- and early Last Glacial (MIS 2) gleyed soil horizons (30–17 ka BP); (5) the final Paleolithic (17–12 ka); and (6) Mesolithic (12–8 ka BP) from diverse geo-contexts.

The earliest Pleistocene sites are associated with old alluvial formations in the Lena and Angara River basins. The Diring Uriah Site sealed in coarse sandy deposits of the 200-m-high terrace of the Lena River is presently one of the earliest sites found in Siberia (Fig. 10). Despite its indefinite chronological assignment ranging from 2.5 Ma to 350 ka (Mochanov 1992), this site eloquently demonstrates a very early peopling of northern parts of Asia in the principal river valleys during some of the Early but surely the Middle Pleistocene interglacials that also promoted northern expansion of mixed taiga and open parklands. The Middle Pleistocene cultural records from the upper Lena and Angara areas, represented by stone artifacts made of quartz and quartzite cobbles with the typical archaic tool forms (choppers, bifaces, scrapers on flakes, polyhedral cores), display strongly wind-abraded surfaces. The age of these cultural assemblages from the Angara region exposed along the Bratsk Lake (the Igetei locality), referred to as of the Acheulian-Mousterian tradition, is estimated to be c. 200 ka BP, corresponding to the Shirta Interglacial/MIS 7 (244–170 ka BP) (Medvedev et al. 1990). A Middle Paleolithic occupation at the Mungkharyma Site (64*N) located on the 70 m terrace of the middle Viluy River produced a well-made stone industry of the Levallois tradition, including bifaces, bifacial knives, and side-scrapers, found with Pleistocene fauna (mammoth, wooly rhinoceros) (Fig. 11). A luminescence date 150 ± 38 ka BP (RTL-958) from the overlying sandy-silt layer suggests a (late) Middle Pleistocene age (Mochanov and Fedoseeva 2001). Climatic cooling, leading to expansion of mosaic steppe and pine-larch parklands, is linked with the onset of the Samarovo (270–244 ka BP) glacial period. A drop of annual temperature and increase in aridity during the Tazov Glacial (170–130 ka BP) hastened the degradation of interglacial forests and extension of open periglacial landscapes. The marked final Middle Pleistocene environmental deterioration is indicated by a cold-adapted tundra-steppe fauna from alluvial deposits including progressive

Siberia: Paleolithic, Fig. 10 The Middle Paleolithic Mungkharyma Site (64*N) on the 70 m Viluy River terrace, east-central Yakutia (Excavations by Y.A. Mochanov 2009)

taxa (mammoth, wooly rhinoceros, bison, horse, kulan, giant deer, argali), as well as species specific to the Trans-Baikal area (the Kiakhta antelope, the Baikal yak, dzeren, camel). Human survival in SE Siberia during the Samarovo (MIS 8) and the Tazov (MIS 6) glacial stages with MAT by up to −10 °C lower than at the present time presumes knowledge of fire making.

Siberia: Paleolithic, Fig. 11 The Middle Paleolithic quartzite tools from central Yakutia (the Kyzyl Syr Culture) (Courtesy S.A. Fedoseeva)

The Middle Pleistocene sites from the central and southern Lena basin and its tributaries (Viluy, Aldan) (Fig. 12) have the principal implications to the initial prehistoric colonization of NE Asia as well as North America.

During the Last Interglacial (MIS 5), mixed taiga forests were widely distributed in the mountain areas, indicating a temperate continental climate with summer air temperatures up to 5 °C higher than at present. Fossil chernozems at the Middle Paleolithic sites Mal'ta and Igetei (MIS 5e and 5c, resp.) illustrate open parkland-steppe settings of the upper Angara basin. Marked cooling, increased aridity, and intensified aeolian activity contributed to accumulations of extensive sandy deposits derived from drying up of river beds in the Irkutsk Depression and the Lena Basin during the early Last Glacial (MIS 4). Cold intervals with increased humidity correlate with cryoturbation processes, solifluction horizons, and pollen records of invading periglacial grasslands and open pine-birch tundra. Despite very harsh conditions, a Middle Paleolithic (Mousterian?) occupation may have locally survived in the Angara area.

Siberia: Paleolithic, Fig. 12 Partly humanly articulated Pleistocene fauna skeletal remains (mammoth, bison, horse) from the Yana River basin, NW Yakutia, providing evidence of the biotically rich mid-Last Glacial North Siberian ecosystems exploited by the Palaeolithic people (J. Chlachula, unpublished data)

The mid-Last Glacial interval (MIS 3), with an early cold and arid loess sedimentation phase (59–40 ka BP) followed by a warm and humid pedogenic phase (40–24 ka BP), brought a major change in the distribution of vegetation zones in East Siberia, with a northern expansion of mixed taiga forests and pine-birch dominated parklands. Broad-leaved arboreal taxa (oak, beech, elm, hazel) distributed in river valleys of the Baikal region attest to mosaic habitats with climate conditions possibly warmer than today. Cultural finds from the principal occupation sites (Ust'-Kova in the Angara basin, Mezin in the Kana valley, Kamenka in the Selenga basin, and the Aldan River complex) dated to 30–24 ka BP display a poor preservation due to cryogenesis and solifluction processes persisting until the onset of late Last Glacial (Sartan) stage (MIS 2). Remains of fauna exploited by people (horse, antelope, wooly rhinoceros, mammoth, bison, sheep-argali, and camel) and rodent taxa are indicative of an open steppe and parkland habitat. At the Kamenka Site, specific site complexes of game-processing, wood-working, stone and bone tool production, mineral paint manufacturing, and other behavioral cultural (ritual) activities were documented (Lbova 1996). The fossil fauna variety from different (mountain) ecotones shows a wide (>100 km) mobility range of the local Paleolithic hunters. A northern expansion of the Late Paleolithic occupation ambit into the extreme parts of the East Siberian Arctic is recorded at the Yana RHS site located 100-km south of the Laptev Sea coast (70° 43′ N, 123° 25′ E). The cultural evidence (stone and bone industry) and fossil fauna sealed in cryogenic silt blocs on the 18-m Yana River terrace and dated to 45–26 ka BP indicate environmental stability and a high biotic productivity of the mid-Last Glacial (MIS 3) interstadial floodplain meadow of the Yana River delta (Pitulko et al. 2004, 2017). This site provides evidence of humans migrating along the ice-free northern coast of Siberia/the exposed continental Arctic shelf. Favorable environmental conditions with boreal forest-parkland biotopes across the continental Siberia during the mid-Last Glacial are supported by isolated paleoanthropological remains indicating an early Upper Palaeolithic occupancy. A male femoral bone eroded from ancient alluvial deposits of the Irtysh River (the Ust'-Ishim Site) points to presence of modern humans in the West Siberian Lowland at least 45,000 yr ago, Its genome sequence points to co-ancestry with the North Asian Neanderthal population (Fu et al., 2014).

During the late Last Glacial stage (MIS 2) – the Sartan Glaciation (24–12 ka BP) – tundra-steppe covered most of the territory occupied by the Late/Final Paleolithic people represented by the famous sites Mal'ta and Buret' in the upper Angara basin (Tseitlin 1979). Climate deterioration with sparse Arctic vegetation and a progressive loess accumulation around the LGM caused presumably a major decline in the population density over East Siberia despite some adaptation indices to extreme periglacial environments (the Krasnyy Yar Site in the upper Angara with animal bones and fossil coal used as fuel) (Medvedev et al. 1990). A periglacial fauna (horse, wooly rhinoceros, mammoth, bison, giant deer, elk, saiga) implies cold periglacial tundra-steppe in the Angara, Lena, and the Trans-Baikal basins. Climate amelioration after the LGM (18 ka BP) is best evidenced by rodents from the Baikal-Angara-Lena Paleolithic sites (Buret', Krasnyy Yar, Igetei, Mal'ta, Bolshoi Jakor) that indicate a gradual transition from tundra-steppe and meadow-steppe to forest-steppe landscapes corresponding to shifts from a cool and dry climate to milder and humid conditions. This warming trend fostered dispersal of the Final Paleolithic complexes during the late Last Glacial (18–12 ka BP) associated with the Diyuktai Culture with microblade stone and bone technologies. The Final Pleistocene recolonization of East Siberia reached the marginal subpolar regions of the NE Arctic (e.g., the Berelekh Site in northern Yakutia at 70° N, dated to 13–11 ka BP or the Zhokov Island Site at 76°N dated to 9 ka BP (Pitulko 2013) (Fig. 13). The broad geographical distribution of the new technologies to the most distant parts of Siberia and the Russian Far East Islands (Slobodin 1999; Ponktratova 2007; Vasilevskyy 2008; Ineshin and Teten'kin 2017) reflects a successful prehistoric adaptation to the Final Pleistocene environments (Fig. 14).

Siberia: Paleolithic, Fig. 13 A view from the Final Pleistocene Kheta Site onto the Kheta valley, the Kolyma Basin, NE Siberia. River valleys served as the main migration corridors during the Pleistocene colonization of the northern territories of Siberia and the Russian Far East (all photos Figs. 2–13 by the author).

Siberia: Paleolithic, Fig. 14 The Mesolithic (early Holocene) Zhokhov Site (76° N), the New Siberian Islands, retaining "Paleolithic" adaptations and bone-processing technologies (2003 excavation). The northernmost located early occupation site in Siberia (Photo courtesy of E. Pavlova)

This process culminated in a spatial spreading and presumably a major population increase by the end of the Pleistocene, represented by the early Mesolithic (11–9 ka BP) hunters and gatherers reaching the extreme parts of the Arctic Siberia. In sum, the geological and biotic climate proxy records document a complex Quaternary evolutionary environmental development in East Siberia as seen in the gradual cultural adaptation of people and the geographic expansion of occupied areas.

International Perspectives

The geological and paleoecological evidences across western, south-central, and eastern Siberia, including the Ob, Irtysh, Kuznetsk, Yenisei, Angara and upper Lena basins and the adjacent regions of the Trans-Urals, Altai, Western and Eastern Sayans Mountains, Baikal Range and the NE Siberian mountains, disclose cyclic climatic changes during the Quaternary leading to establishment of the present environments. A global trend toward a strongly continental climate, with increased aridity and high seasonal temperature fluctuations, is traced since the late Pliocene. The progressing development during the Quaternary Period (the last 2.5 Ma) is evidenced by the zonal geographic shifts in the vegetation distribution, with the expansion of boreal (taiga) forests northward during the interglacial periods and warm interstadials stages, succeeded by the subarctic periglacial forest-steppe and tundra-steppe during the glacial periods with the tree cover confined to refugia in the southernmost areas of Siberia (the Altai and Sayan Mnt. foothills). Complex paleoenvironmental evolution archives are stored in the high-resolution loess-paleosol sequences, pollen records, and fossil fauna remains from deeply stratified alluvial and loessic formations. The loess-paleosol sections on the Altai Plains and the upper reaches of the Yenisei basin have provided most complete information on the past climatic variations, the landscape development, and the associated changes in the Pleistocene biotic communities on the territory of Siberia. The high-resolution stratigraphic records coupled with pollen and paleontology data indicate marked Pleistocene ecosystem transformations, with arctic tundra and forest-tundra during cold stadial intervals replaced by boreal forest and parkland – steppe during the warm interstadial intervals.

The Early and Middle Pleistocene climates brought major transformations of natural habitats, facilitating the northward dispersal of the Paleolithic people from the southern areas of Central Asia and Mongolia, and their environmental adaptation to the Siberian regional settings. The earliest unequivocally documented Middle Pleistocene (Early Paleolithic) occupation followed the main continental basins and the major river valleys. The human dispersal further east and north is assumed to have principally occurred during warm interglacials in the processes of the northern expansion of mixed parkland forests and the associated fauna communities, whereas only local movements of early human groups are envisaged during cold stages. The Tobol (MIS 9) Interglacial (390–270 ka BP), when the MAT was by c. 3–4 °C higher than at present, is likely to have been (one of) the most favorable time periods for initial migration to northern Asia reaching as far north as 60 °N latitude. The Early and Middle Paleolithic finds bear witness of repeated inhabitation of the Irtysh, Ob, upper Yenisei, Angara, Viluy, Vitim, Aldan, and the upper Lena River basins prior to the Last Interglacial. During the late Middle Pleistocene, glaciers in the Western and Eastern Sayan ranges expanded into the foothills to about 300–400 m altitude preceded by a downslope retreat of dark coniferous taiga forests. In the Minusinsk Depressions, the Kuznetsk Basin, and the northern Altai valleys protected from arctic tundra in the north, propitious (although periglacial) conditions with high biomass concentrations of steppe-parklands may have persisted during the glacial stages. This is evidenced by the abundant fossil remains from the Yenisei and Angara alluvia (60–80 m terraces) found with cultural records, as well as a colluvial reworking of the older (late Middle Pleistocene) loess cover, indicative of a fluctuating moderately cold climate regime, not excluding a continuation of the early human inhabitation of these areas.

Within the Last Interglacial (MIS 5; 130–74 ka BP), most of Siberia was covered by coniferous or mixed forests including broad-leaved taxa (lime, elm, oak), with forest-steppe distributed at lower elevations and in river valleys. At that time, the Middle Paleolithic (Neanderthal or early *Homo sapiens*) people entered the territory from Central Asia and/or the East European Plains. Expansion of the occupation habitat into the mountain areas, following the Last interglacial climatic optimum, likely occurred in the later (MIS 5c and 5a) interstadials. During the early Last Glacial (Zyriansk) stage (MIS 4; 74–59 ka BP), cold periglacial tundra/tundra-steppe and continuous permafrost expanded across most of Siberia. The approaching glacial maximum disrupted human settlements, although this may have persisted in some protected southern locations. Following the interval of intensive loess deposition at the end of the glacial, renewed warm climate pulses during the mid-glacial (Karginsk) interval (MIS 3; 59–24 ka) preconditioned formation of zonal soils associated with the transitional Middle/early Late Paleolithic stone industries, suggesting a certain regional cultural (and possibly biological) continuity in the Late Pleistocene Siberia. Moderately cold and stable environments during the second half of the interstadial interval (30–24 ka BP) promoted a major enlargement of occupation habitats marking a climax of the Paleolithic peopling in Siberia associated with the emergence of the "classical" Late Paleolithic cultures. Productive interstadial ecosystems with mixed parkland forests and taiga were gradually transformed into periglacial tundra of the approaching Last Glacial (Sartan) stage (MIS 2; 24–12 ka BP). A reduced population density is assumed around the LGM (20–18 ka BP) hindered by extremely cold climate conditions. Some occupation continuity persisting until the end of the Pleistocene may have applied just for biotic refugia in the protected southernmost locations along the Altay-Sayan foothills. Overall, the spatial and temporal distribution of the early cultural records documents environmental instability over large parts of Siberia during the Quaternary Period (the last 2.5 Ma). Specific geographical and contextual locations of early sites indicate that natural conditions during the earlier periods were generally more favorable for peopling than during the later periods. On the other hand, increased continentality and gradual shifts towards cold and arid conditions accelerated adaptation of the Middle and Upper Paleolithic populations to harsh periglacial climates promoting a progressive development of sophisticated survival strategies and fostering colonization of the extreme Siberian North.

Timing and evolutionary processes related to the initial colonization of northern Asia are still insufficiently mapped, although ongoing archaeological investigations supply continuously new evidence about particularities and general trajectories of this evolutionary process. The traditional views, assuming a very late (Late Pleistocene) inhabitation of Siberia and Beringia, have been definitely challenged. The archaeological discoveries disprove the long-held assumption of a late penetration (by Late Paleolithic people) into the middle and high latitudes of northern Asia. Instead, glacial-interglacial and stadial-interstadial climate cycles regulated a geographic movement of early people northward, predetermining the inhabitability of particular geographical areas. During glacial maxima, most of Siberia seems to have been vacated, especially during the earlier periods, because of the expansion of continental glaciers in the north and inhospitable environments in the southern extra-glacial regions. Gradual adaptation to cold natural habitats accelerated during the Late Pleistocene in connection with the advanced cultural and biological adjustment, enabling people to establish permanently in the vast and geographically diverse Siberian territory.

Future Directions

The studies on the Paleolithic of Siberia have made a major progress during the last 20 years changing radically the once valid paradigm on the Late Pleistocene colonization of north-central Asia. Despite this, most of the presently mapped sites tend to concentrate in the southern geographical regions and reflect a limited accessibility of

the northeastern subarctic and Arctic areas which are, however, of major potential for future investigations also with respect to mapping the initial peopling of the American continent. The evolutionary processes in the natural environments and specific behavioral Paleolithic adaptation patterns and material-technological conditions as well as documentation of the sequenced climatic events stored in geological records are the principal objectives of the current multidisciplinary Quaternary investigations. Equally important are the contextual past climate and paleoecology studies encompassing the last 2.5 Ma, because of increased awareness of the value of regionally reconstructed geological and natural proxy histories for understanding the past and present-day ecosystems and the early human (Pleistocene-Holocene) cultural adjustment strategies to the diverse Siberian environments. The integrated Quaternary geology and geoarchaeology studies are of principal importance for the future field surveys particularly in the marginally investigated areas of Siberia and the Russian Far East aimed at completing the culture-historical mosaic of the early human inhabitation of these geographically very extensive and scientifically fascinating territories.

Sicily and Magna Graecia, Archaeology of

Justin St. P. Walsh
Department of Art, Chapman University, Orange, CA, USA

Introduction and Definition

The Latin term "Magna Graecia" (in Greek, "Megalē Hellas") means "Greater Greece." In the term's first attested usages, by Pindar and Euripides in the fifth century BCE, it applied to all of the territory inhabited by Greeks around the Mediterranean (Cordano 2005). While it has been suggested that "Megalē Hellas" was used as early as the fifth or fourth century to mean only the parts of modern Italy that were colonized by Greeks – the coasts of Sicily, Campania, Calabria, Basilicata, and Puglia – the texts which might have done so, by Antiochus of Syracuse and Pythagoras of Croton, are not preserved today.

The earliest recorded use of the phrase to mean southern Italy and Sicily is thus Polybius (*Histories* 2.39) in the second century BCE, followed by Strabo (*Geography* 6.1.2) and, for the Latin version, Pliny the Elder (*HN* 3.95). Modern scholars tend to be even more restrictive in their usage, employing Magna Graecia to mean

only peninsular Italy where it was settled by Greeks, in contrast to Sicily, which is often considered as a case by itself.

Much of the landscape of Magna Graecia and Sicily is composed of rolling hills and low mountains up to 2,000 m in height. The environment is well suited to a pastoral agricultural economy of sheep and goat herding, supplemented by other animals on a limited basis. Coastal plains were farmed for grain – wheat, barley, and spelt – while hilly areas typically featured olives, grapes, and other plants adapted to the terrain. The climate is generally dry and temperate, with an average annual rainfall of about 40–60 cm.

Key Issues/Current Debates

Bronze Age

The archaeology of the Bronze Age (c. 2200–900 BCE) in southern Italy is largely marked by the transition through successive cultural phases from pre- and proto-Apennine through the Apennine and sub-Apennine periods. The distinctions between these cultural phases do not correspond well to the usual chronological divisions of the Eneolithic (or "Copper Age") and the Early, Middle, and Late Bronze Ages. Dates for the later periods are largely given by the presence of Aegean imports. In the pre-Apennine phase, from roughly 2200 onwards, settlements were placed on low hills to allow control of surrounding agricultural zones. Burials were inhumations in single pit graves organized into cemeteries, and grave goods of a few bronze objects occasionally supplemented by one or two vases. The earliest contacts with Mycenaeans date to the latter part of the proto-Apennine phase, which started in the early second millennium and continued down to c. 1500. Typical imports consisted of Late Helladic I and II pottery. In this phase, the coasts of the Adriatic and Ionian Seas (though not the Tyrrhenian Sea) were the locus of many settlements. Funerary practices comprised a wide variety of types, from caves to tumuli, though in every case, burials remained single inhumations grouped together. The Apennine culture ultimately gave way around 1200–1100 to the proto-Villanovan culture, with the introduction of cremation burials. From 900 onwards, Italic-speaking populations south of the Tiber River developed separately from the Etruscan-speaking groups of central and northern Italy, reintroducing inhumation burials.

In Sicily, the Early Bronze Age (c. 2500–1500 BCE) was characterized by multiple burials in chamber tombs. The primary EBA cultural group was identified with the site of Castelluccio, where pottery had black designs on a red background. As in south Italy, Mycenaean artifacts began to appear between 1500 and 1250 BCE, during the Sicilian Middle Bronze Age. At Thapsos, a town on the southeastern coast with notably large storage areas (possibly indicating thriving commercial activity), Mycenaean pottery was particularly well represented. Locally produced pottery is marked by incised decoration and carinated shapes, most strikingly on large pedestaled bowls with zoomorphic features.

Two major typologies have been identified for the Late Bronze Age (c. 1250–1050 BCE) and the so-called Final Bronze Age (c. 1050–900 BCE): Ausonian, in the north, and Pantalica, in the southeast. Affinities with the Apennine culture have led to the suggestion that the Ausonians, known from tombs and huts on Lipari and the Milazzo peninsula, might have migrated from the mainland (as mentioned by Greek authors). Evidence for the later Sikel language from Iron Age inscriptions indicates an Italic ancestry which could have come to the island at this time. Ausonian culture was characterized by inhumation and cremation burials in large jars. Pantalica represented continuity from the Thapsos culture, with baggy vase shapes and pedestaled bowls, usually with incised geometric decoration. Burial was made in thousands of chamber tombs cut into limestone cliffs (Fig. 1). There is little evidence for settlements in the Late and Final Bronze Ages.

Iron Age

Increased contact with the Greek world began again in the eighth century, with the earliest identifiable artifacts arriving in the form of Middle Geometric cups from Euboia. The earliest Greek

Sicily and Magna Graecia, Archaeology of, Fig. 1 Late Bronze Age rock-cut chamber tombs in the cliffs of Pantalica, Sicily

settlement in the region was made at Pithekoussai, on the island of Ischia just north of the Bay of Naples, in the second quarter of the eighth century. This town, known mainly from the excavation of a cemetery, seems to have been an *emporion*, or a trading post lacking in agriculture. It seems likely that the foundation of the town at this location was meant to facilitate trade with Etruscans who controlled metal production in central Italy and Sardinia. There is strong evidence of Phoenician and indigenous presence at Pithekoussai, the latter particularly in female burials, which might imply intermarriage with local groups from the mainland. The earliest example of writing in the Greek alphabet is known from Italy rather than Greece itself: an inscription, perhaps reading "euoin," was incised on a vessel found in a tomb of the Osteria dell'Osa necropolis near Gabii, in Lazio, and was dated to perhaps as early as 800–770 (Watkins 1995: 37–39). Likewise, the earliest known reference to Homeric myth was found in a dipinto on a Euboian cup (c. 750) found at Pithekoussai. The text, in dactylic hexameters, refers both to the legendary cup of Nestor and to Aphrodite.

The first true colony (*apoikia*, or "foreign home," in Greek) was founded at Kyme, a mainland promontory facing Ischia, around 750. More colonies followed around the coast of southern Italy and eastern and southern Sicily, with new foundations occurring into the sixth century in Sicily and into the fifth century on the mainland. Greek colonies shared cultural ties with their mother city (*metropolis*) and felt some allegiance to their homeland, but an *apoikia* was politically and economically independent. While colonization of Sicily was mostly carried out by only two *metropoleis*, Chalcis and Corinth, expeditions to south Italy originated from a wider swath of the mainland, including Achaea, Sparta, and even (in one late example, Thurii) Athens. Ancient narratives often described colonizing expeditions that were carried out as a result of an oracular instruction from Apollo at Delphi; these were commonly represented as ignorant of the territory that was their destination. In reality, these expeditions demonstrated significant prior Greek experience with the Italian landscape. Colonies often seem to have displaced indigenous settlements, as at Syracuse and Naxos, and were purposely situated to take advantage of flat arable land, good harborage, and river valleys leading into the hinterland. Such advance planning can be identified at Catane, Syracuse, and Gela in Sicily and Poseidonia, Sybaris, and Taras in Magna Graecia. A system of land division existed in each colony

to apportion plots of land to colonists in both their urban and rural areas. Aerial study combined with excavation has brought to light the grid of roadways that were created to divide the countryside of Metapontion; crossroads were marked by groups of tombs. It is not clear to what extent attempts at equitable land division at the time of foundation – as identified, for example, at Megara Hyblaia – reflect political equality among colonists, although some efforts have been made by scholars to suggest it.

Ancient authors (Thucydides, Diodorus Siculus, Dionysius of Halicarnassus, Strabo, and others) identified a number of indigenous groups in Sicily and south Italy at the time of Greek colonization. The Daunians and Iapygians inhabited Puglia, and the Lucanians and Oenotrians were in Basilicata, the Ausonians and Opicians in Campania, and the Sikels in Calabria. In Sicily the Sikels (or the Ausonians or the Morgetians) in eastern Sicily were found, the Sikans in the west, and the Elymians in the northwest. The ancient writers, who were uniformly Greek or Roman, sometimes lacking firsthand experience in the region, and often writing several centuries after contact, did not explain what ethnic or cultural distinctions existed between any of the groups, except to mention divergent lineages extending back to foundational heroes. It is therefore unclear to what extent Greek identifications reflected natives' views of the boundaries between and among themselves.

In striking contrast to the written record, archaeology has not shown significant differences between indigenous groups in Sicily, for example, either before or after contact with Greek or Phoenician settlers. Two types of pottery – one matte-painted, called Siculo-Geometric, or after the type site of Licodia Euboea, and another incised, named for the site of S. Angelo Muxaro, near Acragas – were produced by the indigenous cultures of Iron Age Sicily. Siculo-Geometric seems to predominate in the supposedly Sikel east, but it is also found in the west, while the opposite is true for S. Angelo Muxaro ware. Rather than revealing a strict dichotomy, then, between eastern Sikel and western Sikan cultures, respectively, the archaeological record shows that individual sites should be placed instead at various points along a continuum defined by these pottery types and other attributes. Indigenous settlements were composed of cellular nuclear-family housing, as at Sabucina or Vassallaggi, or longhouse-type dwellings up to 25 m long for extended families, as at Morgantina.

Bronze hoards are one of the most impressive indicators of Iron Age indigenous culture; the most spectacular deposit was the Mendolito hoard of the eighth or seventh century, found near modern Adrano, consisting of over 1,000 pieces (especially spearheads, plaques, belt-like girdles, and other objects) weighing 900 kg. Brief inscriptions dating into the fifth century have been found in Sikel, employing a Greek alphabet.

Greek Colonization

Equality seems to have been the rule in the distribution of land to colonists, with urban plans tending towards orthogonality – even at Megara Hyblaea, where the plan is not orthogonal but the streets were laid out in straight lines, the house lots were designed to be approximately equal in area (Tréziny 1999). Pottery from Corinth and Euboea continued to dominate in Sicily into the sixth century.

Phoenician Colonization

Phoenician colonial expeditions were also sent to Sicily, though not to south Italy. These began around the eighth century, in the northwest of the island, closest to Carthage. Major settlements were founded at Panormus and Solunto and on the island of Mozia in the seventh and sixth centuries. Phoenician towns do not seem to have had strong agricultural components and on the whole were probably less independent than Greek colonies from their mother city. These towns enabled trade between Carthage and Italy and, to a lesser extent, the northwestern Mediterranean instead. Phoenician-style spaces have been found in these settlements, such as a *tophet* (where first-born sons were ritually sacrificed) on Mozia and several cemeteries with rich burials dating from the seventh through the third centuries at Panormus. Solunto's Roman-period settlement shows a

highly Hellenized character, including peristyle-courtyard houses and a theater.

Archaic and Classical Period

The fifth century in both Sicily and Magna Graecia was marked by conflict. In both areas, wars were waged between Greek cities and between Greeks and indigenous groups. The city of Poseidonia was conquered by the Lucani (Strabo *Geography* 6.1.3) at some point in this period, after which the town was renamed Paestum and the two groups lived together, apparently as equals. In Sicily, Greek tyrants fought against each other, against a Sikel league, and against Carthaginians, leading to the destruction or forced evacuation of several major centers. A Carthaginian invasion destroyed many Greek cities between 409 and 405, including Selinous, Acragas, Himera, Gela, and Camarina. Syracuse barely escaped destruction. The appearance of fortification walls across the island, as at Selinous, Gela, Tyndaris, and the Euryalos fort outside Syracuse, is testimony to the violent nature of this period.

Sicilian and south Italian builders began building monumental stone architecture almost as soon as they appeared in mainland Greece. There are Doric temples at Syracuse, Selinus, Poseidonia, and Taras dating to between 600 and 550 (Fig. 2). These early buildings are long and narrow, with small intercolumniations, similar to contemporary mainland temples such as the Temple of Hera at Olympia. Later buildings assumed shorter and wider proportions in their plans (Fig. 3). Colonies often placed extra-mural temples (especially ones dedicated to Hera) on the edges of their territory as a means of sending a message regarding their claim to the land to natives and other Greeks alike (de Polignac 1995). At the same time, however, religious life in Sicily was marked by syncretism of indigenous and Greek beliefs and practices. At Palike, the site of a volcanic spring and an indigenous shrine to chthonic deities, Greek-style buildings including a *hestiatorion* (dining hall) and stoas were built (Maniscalco and McConnell 2003). Greek myth incorporated the worship of female fertility deities around Lake Pergusa by identifying them with Demeter and Persephone; this pair received shrines at sites across the island. A crater rim found at the archaic settlement of Morgantina was inscribed with an inscription in Greek reading "Kuparas emi," "I am (or I belong to) Kupara" (Antonaccio 1997) (Fig. 4). The name Kupara is connected with a Sikel water deity located near Syracuse, perhaps indicating that this Greek vessel had been dedicated as a gift to an indigenous god by a Greek speaker. At the same time, "kupara" can mean "hollow" in Greek, reflecting the crater's large open shape. Such word play was common in the Greek symposium, and thus the inscription can be seen as evidence for linguistic crossing in a mixed cultural environment.

Sicily and Magna Graecia, Archaeology of, Fig. 2 The early Doric Temple of Hera I at Poseidonia (c. 550 BCE)

Sicily and Magna Graecia, Archaeology of, Fig. 3 The Temple of Hera II at Poseidonia (c. 460 BCE)

Sicily and Magna Graecia, Archaeology of, Fig. 4 A Lakonian krater rim from the Archaic settlement at Morgantina (Aidone Museum inv. 90-61) with an inscription in Greek reading "Kuparas emi" ("I am Kupara" or "I belong to Kupara")

By the mid-sixth century, large stone buildings at Selinous and Poseidonia included stone sculpture in the metopes. Both Sicilian and South Italian colonies maintained strong ties to Greece, most clearly in the construction of numerous treasury buildings at the panhellenic sanctuaries of Olympia and Delphi (where they also competed in the games). Sicilian tyrants were especially successful in Panhellenic competitions. Victories were celebrated by sculptures including the Delphi Charioteer (c. 478–474), given by Polyzalos of Gela, and the Motya Charioteer (c. 470). Cities also competed for prestige the construction of massive temples, especially following the Greek victory at Himera over the Carthaginians in 480. Temple G at Selinous and the Temple of Zeus at Acragas vied for recognition as the largest Doric temple in the Greek world. Greek colonies also seem to have featured *heroöns*, or shrines where a colony's founder was worshiped as a hero, in its marketplace, though such a structure is only well identified at Poseidonia.

The lack of marble in the region led to the use of local limestone and sandstone for building material. Sicilian builders made up for the lack of high-quality stone by using brightly colored terracotta revetments and figural sculptures as decoration, such as the relief plaque from the Temple of Athena at Syracuse depicting a gorgon running on bended knee (Fig. 5), and even on structures built in Greece, such as the Treasury of Gela at Olympia. Imported marble was used for smaller works, such as the so-called Ludovisi Throne, which is made of marble from the Aegean island of Thasos. This work, with its remarkable reliefs depicting the birth of Aphrodite flanked by smaller scenes showing a clothed and a nude female worshipper, respectively, was actually one half of the frame for an altar. It was found in Rome, where it had been taken in antiquity. The sculpture's original location has now been determined as the sanctuary of Aphrodite at Lokris (modern Locri Epizefiri). Imported marble was also used for the exposed skin of some sculptural subjects, such as for the heads, hands, and feet of the metope figures of Temple E at Selinous. Free-standing acrolithic sculptures using imported

Sicily and Magna Graecia, Archaeology of, Fig. 5 Terracotta plaque of a gorgon from the Temple of Athena at Syracuse (Syracuse Archaeological Museum "Paolo Orsi," inv. 34540, 34543, 34895, c. 570 BCE)

stone were much more common in Sicily than elsewhere in the Greek world. The most important examples are the archaic Demeter and Persephone from Morgantina and the spectacular over-life-size cult statue, probably of Hera or Demeter, that is claimed to be from the same site (in the Aidone Museum since 2011 but formerly in the J. Paul Getty Museum collection, where it was erroneously identified as depicting Aphrodite) (Fig. 6). South Italian and Sicilian sculptors also created a few free-standing sculptures in marble of youths (*kouroi*) and boys from Akragas and Rhegion which show links to contemporary mainland Greek types like the Kritios Boy from Athens.

The best preserved example of Greek major painting – indeed, practically the only one from the Classical period – was found at Poseidonia, in a grave now known as the Tomb of the Diver (c. 480–470). The interior of the grave's sarcophagus was decorated on its side walls with scenes of a symposium, while the inside of the lid showed a young man diving from a platform into a pool of water, which has been interpreted as possibly being a metaphor for the transition from life to death (Fig. 7).

Sicily and Magna Graecia, Archaeology of, Fig. 6 Over-life-size Greek cult statue of a female deity in limestone and marble (c. 425–400 BCE), today called the "Morgantina goddess"

People in south Italy and Sicily continued to be consumers of imported Greek pottery, primarily Corinthian and East Greek wares (especially Ionian cups – though many of these were also manufactured in the colonies) in the sixth century and Athenian in the fifth. Greek pottery is found in Greek, mixed, and non-Greek settlements and in domestic, religious, and funerary contexts. In the fourth century, with the decline of Athenian exports of painted pottery due to the crisis following the Peloponnesian War, south Italian and Sicilian production grew significantly. In southern Italy, regional groups have been distinguished (especially by A.D. Trendall and A. Cambitoglou) for Apulia, Lucania, Campania, and Poseidonia. The red-figure painted decorations featured mythological stories and especially scenes from theater productions – testimony to the popularity of drama in the western Mediterranean.

Sicily and Magna Graecia, Archaeology of, Fig. 7 Interior of the lid of the sarcophagus from the burial known as the Tomb of the Diver, Poseidonia (National Archaeological Museum, Paestum, inv. 23103, c. 480–470 BCE)

The existence and importance of democratic institutions is evident in many cities throughout both regions at various points in time. Both Poseidonia and Metapontion built large circular assembly structures (*ekklesiasteria*) of a type that may be related in some way to the shape of the Comitium at Rome. At Morgantina, large flights of stone steps that mitigated the sloping terrain of the city's agora were arranged in a trapezoidal form starting at the end of the fifth century so that they could also be used as seating for the citizen assembly to hear speakers.

Interpreting Cross-Cultural Relations, 800–400 BCE

In the nineteenth and early twentieth centuries, scholarship was defined by the prevailing colonialist attitudes of the time. Greek colonists were seen not only as members of one of the two ancestral societies of western civilization (the other being Rome) but as the initial transmitters of their cultural traditions to the Romans. Greeks appeared urbane, cosmopolitan, and sophisticated compared to the natives they met in Sicily and south Italy. At the same time, scholars approached the process of ancient colonization as analogous to modern colonialism, particularly as carried out by the British empire, where colonies existed for the purpose of controlling and exploiting far-off resources on behalf of the colonizing nation (Dunbabin 1948). For the purposes of historical explanation, then, Greeks were the primary, if not the sole actors, and either indigenes passively received Greek culture or they abandoned their own traditions in order to become as similar to Greeks as possible. The latter process was identified as "Hellenization," a local variant of what anthropologists elsewhere in the world referred to as acculturation. It is true that indigenous populations adopted Greek practices and material culture, and at least in Sicily from the fourth century on, it is no longer possible to distinguish between Greek and indigenous cultures in the archaeological record (Antonaccio 2001). Siculo-Geometric and S. Angelo Muxaro pottery were no longer made, for example, and the shapes and fabrics that survived were Greek.

Recognition of this broad phenomenon has often obscured other important facts, however: first, natives did not abandon their own culture wholesale, but selected aspects of Greek culture that they found useful within their own societies; second, in southern Italy, the process was never fully completed, particularly because Magna Graecia was ultimately conquered by the Romans, who were themselves an Italic group like those who were neighbors to the Greeks; and third, Greeks were also open to adopting some native ideas and traditions, even in Sicily – for example, the greater emphasis on worship of Demeter and Kore in the island's center because of the importance of similar deities for Sikels. Athenian potters made vases in indigenous forms, such as the pair of *nestorides* (an ornate Daunian shape) in the Getty Museum collection (since the findspot of these vases is unknown, it is not clear whether

Sicily and Magna Graecia, Archaeology of, Fig. 8 Athenian red-figure vase in a Daunian shape, the *nestoris* (Attributed to the circle of the painter Polygnotos, c. 450–440 BCE; J. Paul Getty Museum inv. 81.AE.183.2)

they were intended for indigenous or Greek buyers) (Fig. 8). So acculturation was not inevitable, nor was it a one-way street. Beginning in the 1980s, Classical archaeologists began to adopt new theoretical perspectives from other branches of archaeology, especially world-systems theory (Cunliffe 1988). More recently, others have focused on the altered meaning imported objects could be given in new cultural environments, with the process of meaning change given the name "consumption" (Dietler 1999). In these ways, the ability of indigenous populations to make active choices about how to shape and interpret the world around them has been acknowledged and integrated into scholarly discourse about ancient colonization.

The Hellenistic Period

Southern Italy came under Roman control as a result of victory in the Pyrrhic War in 272. Links to Rome grew quickly from the time of the construction of the Via Appia to Capua in 312 and the road's extension to the heel of Italy and the port of Brundusium in 264. Little evidence has appeared to differentiate south Italian culture in this period from what came before it, however, apart from the wide distribution of mass-produced moldmade terracotta figurines at Taranto (Graepler 1997). These sculptures, known as the Tanagra type, generally depicted women in various activities, especially moving rapidly, dancing, or twirling – perhaps to be interpreted as religious or dramatic action. They were exported across the Mediterranean.

Both regions suffered greatly during the First and Second Punic Wars, with several major cities being sacked and their populations sold into slavery. The main exception was Syracuse, which remained independent and prosperous until the death of the tyrant Hieron II (270–215). The kingdom of Syracuse's wealth is shown by evidence from Morgantina, which underwent great development under Hieron's rule. Several public buildings including stoas, granaries, and a fountain house can be dated to this period. A private house at Morgantina revealed the earliest known tessellated mosaics, dating to the mid-third century, and, perhaps most significant, a bath complex built at the same time was found to incorporate the world's earliest known self-supporting domed roof, constructed of interlocking tubes (Lucore 2009). Although these examples are so far known only from Sicily's interior, it appears likely that the innovations of tessellated mosaics and domes were made at Syracuse. Extant monuments known from Syracuse itself in this period include the theater and the 200-m-long Altar of Zeus Eleutherios. Some of the most distinctive cultural products of the Hellenistic period were the pottery produced at Centuripae. This ware, developed in the third century, employed a wide range of bright colors to produce realistic scenes comparable to Hellenistic wall painting, and it was further adorned with ornate molded pieces.

One important trend that is clearly visible in the Hellenistic period was related to the domestic sphere: the size and development of housing. Hellenistic houses tended to be considerably larger than their Classical predecessors, and they included new features, such as second stories and particularly courtyards with a peristyle colonnade, as seen at Megara Hyblaia, Solunto, and

Monte Iato. The latter site featured a house with an area of 800 m^2.

The Roman Period

The result of the shift in control to an external power was the advent of peace, if not necessarily prosperity, for both Greeks and non-Greeks by the second century. Sicily became the first Roman province in 241 BCE, and Roman military forces completely conquered Sicily by 211. The island was seen by Rome as a significant source of grain. As a result, slave-run *latifundia* became a dominant part of the economy (though slave revolts occurred twice between 135 and 100). The cultural and economic wealth of pre-Roman Sicily was famously looted in the first century BCE by the governor Verres (Cicero *Verrine Or.*). Overall, the island seems to have been in serious decline during the empire perhaps initially because most cities supported Sextus Pompey against Augustus during the civil war. The town of Centuripae, however, thrived following Augustus' victory; it alone had been a supporter of the emperor. The town was given control of much of the Catania plain, which led to a building boom in the town, including a large public building (perhaps a *porticus*), baths, and a large suburban nymphaeum (Wilson 1990). There were few other Sicilian centers in this period; Halaesa is the best known, though it, too, had seen its greatest flourishing under the Republic rather than the empire.

The most important archaeological sites for this period in south Italy are undoubtedly the ones destroyed by the eruption of Mount Vesuvius in August of 79 CE, especially Pompeii and Herculaneum. The Via Appia's route was altered under the emperor Trajan in the second decade of the second century CE. The new road split from the old one at the town of Beneventum in order to take a shorter route across the Apennine mountains to the southern ports that linked Rome to the eastern empire. The construction was commemorated by a triumphal arch at Beneventum, decorated with relief sculptures showing the good deeds and welfare projects undertaken by Trajan on behalf of Italians. Saepinum, not far from Beneventum, is a well-preserved Roman town in the mountains of Molise, complete with remains of a basilica, a small theater, and walls built under Tiberius in the masonry style known as *opus reticulatum*.

Late Antiquity

Sicily is best known in late antiquity for several large villas, especially the Villa Casale at Piazza Armerina, where the largest extant collection of mosaic floor decoration has been found. The luxurious nature of the Villa Casale's architecture and decoration led to the initial hypothesis that it belonged to a member of the imperial family, perhaps even one of the Diocletianic tetrarchs. The discovery of similar complexes at Patti and elsewhere shows it instead to be simply the grandest example of a *latifundium* headquarters, owned by a well-connected Roman family. Similar complexes existed in southern Italy (just as they did in Spain and elsewhere); the best known of these is at San Giovanni di Ruoti, where three villa houses were built on the same site between the first and sixth centuries CE. Christianity was well established by the time of Constantine, and catacombs dating as early as the third century are known from Palermo and Naples.

Sidibé, Samuel

Daouda Keita
Département d'Histoire et d'Archéologie, l'Université des Sciences Sociales et de Gestion de Bamako, Bamako, Mali

Basic Biographical Information

Born in Diaramana (Cercle of Bla) in 1952, Samuel Sidibé (Fig. 1) is the Managing Director of the National Museum of Mali. After his secondary studies in Mali, Dr. Sidibé received a postgraduate scholarship, which took him first to Clermont-Ferrand (France), where he obtained a Masters in Art History and Archaeology in 1975, then to the University of Paris I Panthéon Sorbonne for his doctoral studies between 1976 and 1980. He defended a thesis on the theme of funerary archaeology *Archéologie funéraire de l'ouest africain: sépultures et rites*.

On his return to Mali, Samuel Sidibé worked at the Institut des Sciences Humaines (ISH) as a researcher from 1981 to 1987. In this capacity, he actively participated in field missions and was involved in a project to create an inventory of archaeological sites in the lake region and

Sidibé, Samuel, Fig. 1 Samuel Sidibé, at his office in the National Museum of Mali

the Inner Niger Delta. The launch of this project coincided with his arrival at the ISH. During the same period, Dr. Sidibé was responsible for courses in Art History at the National Institute of Arts (INA) in Bamako, Mali. In 1987, he was appointed Director of the National Museum.

Dr. Sidibé is an active a member of several professional associations and organisations at the national, sub-regional, and international level, including the International Council of Museums (ICOM), the International Council on Monuments and Sites (ICOMOS), and the West African Association of Archaeology (WAAA). From 1993 to 2003, he was a member of the AFRICOM (International Council of African Museums), working group, the program of the ICOM (International Council of Museums) for Africa and He was a founding member of AFRICOM as an association and Dr. Sidibé was a member of the scientific committee for archaeological research at the Dia site in the Inner Niger Delta (1998–2002) and of the committee for the rehabilitation of earthen architecture. He has been a member of the screening committee and the acquisition committee at the Musée du quai Branly in Paris, a member of the Advisory Board of the World Festival of Negro Arts (2007–2009), and a member of the Commission of French archaeological excavations abroad (from 2008).

Major Accomplishments

As the head of the National Museum of Mali, Dr. Sidibé brought about profound changes in the management and operation of this institution. The National Museum, a showcase of Malian culture, is now open to the world and has become a place for encounters between, and dialogue about, cultures.

Dr. Sidibé made a considerable contribution towards enhancing the museum's collections by implementing some major research projects and initiating collections on material and immaterial culture. These projects generated research and collections on musical heritage (1991–1996), traditional pottery (1992–1994), material culture of the Dogon people (1996–1997), and ornaments (2008–2010). Taken together, these collections make a substantial contribution to the preservation of culture in Mali. Since 2005, Dr. Sidibé has opened the National Museum to modern art, making it one of the few African museums to have a collection in this domain.

In addition to developing major new collections, Dr. Sidibé's contributions to the National Museum have included expanding and renovating its premises aimed to support the museum's increasing role in promoting of Mali's cultural heritage. This included the opening of new exhibition space as well as a multipurpose hall, the construction of a storehouse for archaeological objects, the redevelopment of the Koulouba caves in the prehistory garden, and the development of the Point G cave as a place to visit. New initiatives in respect to the museum's cultural activities included a revitalization in visitor programs for school groups, aimed at educating young people about the discovery, study, and understanding of Malian cultural heritage. Another public outreach program "Musical Thursdays," was initiated to make the museum more accessible to the public. Every Thursday afternoon from October to May the stars of Malian music perform at the National Museum.

The National Museum of Mali remains true to its original purpose, namely, the dissemination and promotion of Malian cultural heritage. At the same time, it presents many international

exhibitions, one of which includes the exhibition Vallées du Niger (1991–1997). Dr. Sidibé was the Deputy Commissioner and Coordinator of the African itinerary for the exhibition which travelled through Mali, Burkina Faso, Nigeria, Mauritania, Guinea, and Niger. Since 2009 the National Museum has hosted the African Photography Biennial and Dr. Sidibé has been the General Delegate of the "Rencontres de Bamako".

Siega Verde Rock Art Sites

Rodrigo de Balbín Behrmann and Jose Javier Alcolea-González
Area De Prehistoria, Facultad De Filosofía Y Letras, Universidad De Alcalá De Henares, Madrid, Spain

Introduction

The discovery of Altamira Cave in 1878 opened the door to an understanding and appreciation of Paleolithic art and perhaps toward other kinds of prehistoric graphic representations. It marked the beginning of an appreciation of the intellectual capacity of prehistoric people which, until then, was neither known nor accepted. This is because prehistoric art is not only an aesthetic manifestation but much more; it is evidence of the cognitive and communicative ability of ancient humans.

Following that first discovery, which was not acknowledged for many years, the model of Paleolithic art became linked to cave environments as its sole location and created a concept of location and behavior that would endure until the present time. This has caused an inertia that has been difficult to overcome because it has become so rigid.

Leading scholars of Paleolithic art, including Breuil, Laming, and Leroi-Gourhan, interpreted the manifestations with constructive theories that referred to graphic behavior inside caves and religious categories derived from its location and consequent mystery.

By chance, in 1981 a team from the University of Oporto discovered an engraving of a horse in a clearly Paleolithic style, but in the open air, on the banks of a reservoir on the River Douro, by the dam at the border near Aldeadávila. The evidence was limited, an isolated image in an unsuspected location, but it suggested the existence of Paleolithic representations outside caves or the protection of any rock-shelter.

Although this was initially not adequately assessed or accepted, it signified a revolution in

Paleolithic art, as it implied a new groundbreaking interpretation of the way of understanding that communication system. The graphic manifestations of the Ice Age did not need caves to hide from the general view of people, but were there to be seen and understood by everyone who visited those places. It was the start of a change which began slowly but later picked up speed with the addition of the sites of Domingo García, Piedras Blancas, and Fornols Haut, respectively, in the Province of Segovia, in Andalusia, and in the French Pyrenees (Balbín 2009).

In 1989, Manuel Santonja, then director of the Museum of Salamanca, located the first engraving in the open air at the site of Siega Verde. This figure of a horse was the start of the exploration of the site and the subsequent discovery of 443 figures, through the documentation carried out by the Prehistory Department at the University of Alcalá de Henares (de Balbín and Alcolea 1992) (Figs. 1 and 2).

Siega Verde was not the first open-air site with Paleolithic representations, but it was the first large ensemble of panels to be studied methodically. The research was interrupted between 1995 and 2005 due to the incomprehension of the administration in the Autonomous Community of Castilla y León. However, despite this interruption, work continued, and in 2006 the first complete study of a site of this size and characteristics was produced. Additionally, all the previous research continued, at a site that was justly assessed for the first time from the perspectives of its significance and chronology. Other sites were discovered, like Côa, Zézere, Ocreza, Sabor, Tras-os-Montes, and Foz do Medal in Portugal and Molino Manzanez in Extremadura and Piedras Blancas in Andalusia. It became possible to characterize open-air Paleolithic art first in the area of the Portuguese-Spanish border and then in other places. This is the area with the best schist outcrops in the Iberian Peninsula and where most archaeological surveying has taken place, following the first discovery at Mazouco.

Since the discovery of the site of Côa, close collaboration was established with its researchers, and the study at Siega Verde took into account the reality of the neighboring Portuguese site. Côa was designated World Heritage in 1998 and Siega Verde was listed in 2010 as an extension of the first designation. Once again both sites, 60 km apart in a straight line, were linked in a joint action, in which the Portuguese site and administration moved more quickly.

Siega Verde Rock Art Sites, Fig. 1 Map of Spain with Siega Verde indicated

Siega Verde Rock Art Sites, Fig. 2 Map of Siega Verde, decorated ensembles and fluvial sections

The Site of Siega Verde

The open-air Paleolithic site of Siega Verde is located in the middle-upper valley of the River Agueda as it flows through the municipalities of Villar del Ciervo and Villar de Argañán. Its geographic coordinates are 40° 41′35″ N/02° 58′ 28″ W on the 1:50,000 sheet of the national topographic map (Sheet No. 500, Villar del Ciervo) (Fig. 3).

It is in the tertiary depression of Ciudad Rodrigo, basically a dissymmetric tectonic graben, with its faulted southern edge at the foot of Peña de Francia, whereas the northern edge is gentler and gradually connects with the peneplain of Salamanca. It is a large depression, about 40 km wide, filled with detrital sediment whose upper layer is Pliocene and in which the Quaternary fluvial network, principally the River Agueda, has cut down. The site's location in the northern part of this geomorphic unit connects it with the Arribes del Duero. These are near the border with Portugal, where the River Douro and some tributaries, like the Tormes, Huebra, and Agueda, cut down into the base rock, which reaches a thickness of 300–400 m, forming steep escarpments.

This is a strategic position, as it is on the route to the peneplain and the southwestern depression in the basin, whereas toward the north, only the river network can be followed as it gradually cuts

Siega Verde Rock Art Sites, Fig. 3 South view from the brdige of Siega Verde

down as far as the confluence of the Douro and the Agueda. This position did not go unnoticed by the Paleolithic inhabitants of the region nor by the herds of animals they hunted.

The archaeological surveying covered a large area on the banks of the River Agueda as it crossed the municipalities of Villar de Argañán, Villar de la Yegua, Castillejo de Martín Viejo, Saelices el Chico, San Felices de los Gallegos, and Puerto Seguro. In the end, the site was delimited to an area about a kilometer long, centered on the road bridge connecting Castillejo de Martín Viejo with Villar del Ciervo, in which originally 17 zones with engravings were established, all on the left bank of the river. The rest of the surveyed area did not provide the same results although some schematic engravings were found on a rock outcrop upstream of the Puerto Seguro bridge.

Later research studied the rock art comprehensively in the years 1991, 1992, 1993, 1994, 1996, and 2005, with the result of 15 interim papers and a definitive monograph (Alcolea and Balbín 2006).

The site of Siega Verde is on the banks of the river, with the engravings on outcrops on the banks. These are formed by ferruginous schist that creates quite regular surfaces, often stained red due to exudations from the substrate.

The incision of the river into the Paleozoic schist beds has produced a series of rock terraces which are fluvial erosion planes (Fig. 2). Three terrace formations have been documented at the site. The first (level + 10 to 15 m) is the oldest and is covered by slope deposits. The second (level + 2 to 3 m) is covered by fluvial flood deposits, while the third and most recent is at the level + 0.5 m. The +2 to 3 m level is represented by large river potholes with remains of recent floods. The engraved figures are often found in these areas and are altered at their base by the erosion. The structure in the valley bottom is very rigid, and together with the river regime, this produces rapid disturbance of the sediments in the riverbed, which does not allow the preservation of any type of archaeological deposit contemporary with the artistic representations.

Siega Verde Rock Art Sites, Fig. 4 Panle 3 discovery horse

The southern sector at Siega Verde, with only five decorated surfaces, is about 300 m long, between the first horse to be discovered (Fig. 4) and the medieval Pedrogordo Mill. The small number of surfaces in this sector may be connected with the construction of the mill, as old engravings have been documented on the stones in the building.

The central sector, with the largest concentration of decorated panels, occupies the next 400 m of the western river bank, from Pedrogordo Mill to the water-level station of the Douro Hydrographic Confederation, 200 m upriver. This is the easiest place to wade across the river, where also in the early twentieth century a road and a bridge were built. A pillar of the bridge is supported on rocks with Paleolithic engravings, which have been partially covered and fissures have opened up in the rock surface. The decorated surfaces generally face toward the east and are mainly large outcrops parallel to the river and the large potholes, most of which have been eroded.

The northern sector is in the 200 m separating the River Agueda water-level station and the last panel that has been documented and includes Panels 54–91. As in the other two sectors, the representations are on the left bank of the river, except for Panel 91, on the right bank. The topography is different from the other sectors because the river flows between narrow sides. In this sector the outcrops are large masses of schist with larger upper surfaces and vertical faces toward the east. The Quaternary artists used both types of surfaces. In the case of the former, they used their flat orientation and shape, with numerous concavities and lines of projections caused by erosion. These projections were formed when the riverbed was at their level, at a time before the Paleolithic engravings were produced.

The ensemble of decorated surfaces and its characterization as produced by Upper Paleolithic hunters are overwhelming evidences within the study of the Upper Paleolithic occupation of the Castilian Plateau. Advances in research in the last two decades have approached a panorama of occupation and graphic development that is much more complex than traditionally accepted. We can now affirm that the interior of the Iberian Peninsula was permanently occupied during the second part of the last Ice Age and that this occupation was original and did not depend on other, better-known parts of Iberia, such as the northern or Mediterranean coasts.

Techniques Used

Pecking

The rock art at Siega Verde is currently seen to be engraved. However, the monograph on the site stressed that it was impossible to reach a definitive conclusion about this aspect (Alcolea and Balbín 2006: 187–188). Apart from the difficulties for the conservation of Paleolithic pigments, many of the outcrops were reddish in color and these were used for the engravings. This coloring must have held a special interest for the artists.

In 2007, the pigments were analyzed at the IPH of the Spanish Ministry of Culture. The results confirmed the presence of iron and manganese oxides in Panels 46, 48, and 49. The samples also contained phosphates, apatite, and silicates originating in clay. Neither the manganese nor the other components are natural to the site. Painting existed at Siega Verde and must have been extensive in its use to accompany and highlight the engravings. The incised engravings may have served to frame the painted surfaces.

In the current state of our knowledge, the site contains 443 Paleolithic depictions, of which 244 are animal representations, 165 more or less are complex abstract motifs, and 34 are indeterminate forms with no evident figurative intention as well as 3 anthropomorphs. Of these, 72.23% were produced by pecking the rock, 26.18% by incision, and 1.58% by combination of both techniques (Fig. 5).

Equids and bovines were pecked in all the sectors and ensembles, as well as most of the complex signs. Incision appears to have been reserved for certain motifs, such as caprids, the cervids in the central sector, and some types of sign also found mostly in the central sector.

Pecking is therefore the technique that predominates in the Siega Verde ensemble. It is a fully Paleolithic technical procedure, often ignored or even said to be unknown during the last Ice Age (Alcolea and Balbín 2006: 193–196). This controversy has rapidly lost its relevance because of the discovery of the open-air sites in the Douro Valley and also because it has been demonstrated that this technique was frequently used from the beginnings of Paleolithic rock art in France. Studies by such researchers as the Dellucs (1991) have repeatedly shown this.

Pecking may be direct or indirect. In the former case, the rock was impacted by a hammerstone held directly in the artist's hand. In the latter, a stone is held against the rock and struck by a second heavier stone.

The presence of direct pecking at Siega Verde is quite a novelty, as it is generally agreed that the indirect technique was used in the Paleolithic. However, it is likely that some discontinuous pecking, forming shallow and rounded lines, may have been produced with that technique. Discontinuous lines with separate impacts were usually produced by direct pecking, whereas the continuous outlines may have used both techniques.

Most of the figures at Siega Verde were drawn with continuous pecked lines, like those produced by indirect percussion. Other techniques, like abrasion, were organized around this indirect pecking. The ideal technical process would begin with a linear sketch, which was emphasized by direct percussion and the definitive production of the lines by indirect percussion. This *chaîne opératoire* was completed in a single figure at the site by later abrading the outline (Fig. 6).

The art is therefore fundamentally linear, at least as it appears today. Two possibilities existed to complete the figures: using certain shapes of the rock surface to achieve a sense of volume and conventional modes, which aimed to highlight particular parts of the anatomy.

The first approach was seldom used and is almost exclusively circumscribed to the northern sector of the site. The second, also unusual, is a more advanced and compete procedure. The conventionalisms of the figures are essentially linear, although some of them suggest a more elaborate treatment. In this case, the pecked lines possess fainter outer edges. They are lines achieved by subtle and light percussion, which formed lines of variable depth and width and are able to differentiate certain anatomical parts.

Here, despite the generalized tendency toward pure lines, more complex treatments were introduced. As occurs in the figures painted with dotted lines in the north of Spain, a technique that

Siega Verde Rock Art Sites, Fig. 5 Percentage of representations and types of figures

Siega Verde Rock Art Sites, Fig. 6 Pnale 4 abraded bull

evidently converges with pecking, the width of the outline may have a pictorial value.

From this perspective, the absence at Siega Verde of graphic procedures that are found at some nearby sites, such as the frequent abrasion of pecked lines at Côa, may be explained as a stylistic option. The formalization of the deep outline would annul all the possibilities of expression that appear incipiently at the site. It shares with its Portuguese neighbors a basic concept as regards the production of the figures, and yet it seems more complex from the point of view of the expressive treatment. This complexity becomes clearer if we observe the selection of themes produced with pecking, mainly representations of horses, bovines, and complex signs.

On the River Agueda, pecking may be a substitute for the paintings in the decorated caves. This does not mean that we rule out the original existence of paintings at the site, as they may have accompanied both pecked and incised figures. All this suggests two basic characteristics of the pecking technique at Siega Verde: its value as an incipient expressive resource and its profound conventionalism. Any attempt to explain pecking as an obligatory adjustment to the conditions of the rock surfaces, or to nuance its value as a form of expression in comparison with other techniques employed in European Paleolithic art, cannot be maintained if the data from Siega Verde are analyzed (Fig. 7).

Incision

Our classification, based on the one used by R. de Balbín and A. Moure in their study of Tito Bustillo Cave in Asturias (Balbín and Moure 1982), considers single simple lines, repeated simple lines, striations, and scraping, both of outlines and modeling. The techniques are also compatible.

The percentage of incised engravings in the total number of figures at Siega Verde is 26.18%. These engravings are distributed unequally both spatially and thematically. Only 15.61% of the figurative representations at the site were drawn with direct incision. The percentage increases to 41.61% in the case of abstract depictions and decreases again to 19.19% in the indeterminate motifs.

Single simple lines predominate absolutely, as they are seen in 78.28% of the cases. Repeated simple lines are also present with a percentage of 17.82%, whereas other more complex forms appear very occasionally (striations, 1.66%; scraping, 2.32%). Therefore the incised art is very simple technically, and the more complex

Siega Verde Rock Art Sites, Fig. 7 Panel 89 horses in galope

Siega Verde Rock Art Sites, Fig. 8 Panel 51 grooved deer head

modalities play only an auxiliary role. They appear mainly in animal representations and particularly in large cervids, where repeated lines, scraping, and even striations are used to emphasize some anatomical parts (Fig. 8).

Incision is used in very similar percentages in the different themes. Only a few themes are exclusively pecked (carnivores, rhinoceros, and some complex groups). No group reaches over 10% among the animals, where equids, cervids, and indeterminate quadrupeds predominate, whereas the other animals rarely reach over 5%. Among the abstract representations, a group formed by lines and series of lines stands out with 31.89%, while two other relatively important groups are toothed signs and "darts."

Some subject matters prefer incision. These themes are cervids: stags and hinds, whereas the

reindeer at the site are exclusively pecked, and ibex. Claviforms and dots are never produced with incision, whereas circles and ovals are only incised in a third of their representations. As these signs are the most numerous among the complex abstract representations, the participation of incision in their creation is insignificant.

Again it must be stressed that the use of technical resources at Siega Verde was based on nonmaterial criteria, in connection with the values that each theme held for the Paleolithic artists. This concept underscores the profound conventionalism of the techniques at the site, as remarked above in relation with pecked engravings.

The techniques at Siega Verde are quite coherent with the patterns of Paleolithic art in caves. The differences are only nuances, and in many cases the great geological differences between the two environments are solved by peculiar systems to make use of the relief, as occurs in the northern sector at the site, where the morphology of the horizontal surfaces was systematically used to create figures.

The fully open-air nature of the site and its adaptation to a particular geological reality do not imply a conceptual change from the decorated caves. The apparent dissimilarity is only in the forms and does not involve the use of other technical procedures. Pecking was a well-known technique among European Paleolithic artists, and only the different visual appearance in soft and hard rocks suggests divergences between Siega Verde and more classic sites. The techniques and composition at Siega Verde are Paleolithic in their overall conception and very different from other pre- and protohistoric engravings in all Europe.

Subject Matter

Figurative Representations

The range of subject matter at Siega Verde is relatively limited. It is restricted to several of the typical species in European rock art: equids, large bovines (aurochs (*Bos taurus)* and bison (*Bison bison*)), cervids (red deer (*Cervus elaphus*), reindeer (*Rangifer tarandus*), and giant deer (*Megaloceros giganteus*)) (Fig. 9), and caprids, where the distinction in wild goats between *Capra ibex* and *Capra pyrenaica* is virtually impossible. These four genera contain most of the animal iconographic information, although

Siega Verde Rock Art Sites, Fig. 9 Panel 67 reindeer and horse

Siega Verde Rock Art Sites, Fig. 10 Panel 69 wooly rhinoceros

some more unusual species are found, such as woolly rhinoceros (*Coelodonta antiquitatis*) (Fig. 10), fox (*Vulpes vulpes*), bear, and large felines, but always in much smaller percentages. The high percentages of the equids and cervids are noteworthy. The importance of the latter in the center of the Iberian Peninsula is well known. The numerical differences between the animal themes at Siega Verde and European Paleolithic art in general (more equids than bovines and similar numbers of bovines and cervids) equate Siega Verde with the Paleolithic art in the Iberian Plateau and most European art at that time, despite the different locations.

However, the site does possess some peculiarities in the subject matter. These include representations of extinct species (woolly rhinoceros, bison, and felines) or species that had moved away (reindeer), which is unusual on the plateau. The presence of three human representations is equally noteworthy although these are found at sites on the plateau, such as Los Casares, La Hoz, and La Griega (Balbín and Alcolea 1992: 420; Alcolea and Balbín 2003: Figs. 5 and 7; Corchón, *coord.* 1997: Fig. 194–1 and 2), and even in the open air at Côa, at Ribeira de Piscos to be precise (Baptista 2001: Figs. 4 and 5).

This monotonous range of animals displays significant spatial variations at the site. The central and southern sectors differ from the north as they possess two particular iconographic models. The first is in the central sector, where the trio equids-aurochs-stags creates a monotonous panorama in which only caprids appear sporadically and, to a much lesser extent, unusual animals such as the giant deer, felines, a bear, and a fox. The second model, in the north, is richer and includes reindeer, bison, woolly rhinoceros, bears, and felines. The model is gradually imposed as we move further north in the site.

Siega Verde thus corresponds quite closely to the paleoclimate conditions in the Iberian Plateau during the upper Würm: a large and varied landscape with vast cold steppes and more sheltered areas. Another publication (Alcolea and Balbín 2006: 247) stresses that the plateau was not the environmental desert that it has traditionally been thought to be. In addition to the highlands appropriate for steppe forms of life, microclimates must have produced ecosystems in sheltered areas for more general species. These sheltered environments would be found in the valleys of the plateau's fluvial network, which would also have acted as the routes for contacts and movements across inland Iberia.

The chronological significance of some of the species represented should be analyzed from the perspective of the cultural conditions, in which direct economic or ecological imperatives have little influence. From this point of view, certain animal themes, such as horses and large bovines, appear to persist, whereas other lesser and

complementary themes vary in their frequency spatially and temporally.

In the absence of paleontological data, any study will necessarily be limited. However, one animal is often represented at the site: red deer. Data from other sites on the plateau are similar. Red deer are important and numerous in the caves of Los Casares, La Griega, El Reno, and the more southern Cueva del Niño. This persistence in time, and its coexistence at times with almost arctic fauna, implies that this species was able to live in extreme conditions and that the choice of the subject matter did not correspond directly to the climate conditions but to the cultural preferences of the group.

The appearance of reindeer in Paleolithic iconography has been explained in different ways, but usually appears to be indicative of very cold conditions. Depictions of this animal are not very common and are said to belong to two cold episodes in particular, the Dryas I a or inter-Laugerie-Lascaux (18,000 BP) and the Dryas II (Moure et al. 1987: 91), which does not necessarily mean that reindeer were absent at other times.

The representations of reindeer appear most in the northern sector of the site, together with bison and woolly rhinoceros. There may be a conceptual or even chronological separation between the sectors. This is the case at the cave of La Hoz (Balbín et al. 1995: 44), where finely incised small reindeer and bison are superimposed on previous figures. In El Reno Cave, also in Guadalajara (Alcolea et al. 1997a: 255), an archaic group of paintings and engravings are in a Gravettian style, over which a more recent phase of engravings and paintings, including reindeer, is superimposed. These similarities illustrate the coherence between the cave art on the plateau and its expression in the open air.

The fauna of extreme conditions represented at sites on the Iberian Plateau is documented in late periods with Paleolithic art, because of a harsher climate but always because of the composition criteria. The appearance of the two large bovines represented in Quaternary art was explained by A. Leroi-Gourhan (1971: 462) through two arguments: one geoenvironmental and the other chronological. The increase in the numbers of bison would depend on the latitude and the chronology, as their presence increased in time. This does not explain very well the fact that both bovines depend generally on the same cold ecosystem, although aurochs display a greater capability to adapt.

On the plateau, aurochs are the only bovines documented in archaic phases and are mostly represented in La Griega Cave (Corchón, coord. 1997: Table 1) and in the open air at Foz-Côa (Baptista 1999: Table 4), whereas bison appear at sites with a later stylistic attribution. However, the composition of the subject matter at Siega Verde corresponds to the ecological reality of the Iberian Plateau throughout the last Ice Age and not to the artistic representation of a particular biotope. The depictions coincide closely with the usual situation on the plateau, with a large number of horses and abundant red deer, and differences would mainly be the consequence of chronological changes.

Within their own original appearance, the animal themes on the plateau clearly share some of the stylistic traits seen in the whole Franco-Cantabrian region. The stylistic analogies with the east and south of the Iberian Peninsula gradually disappear over time, and it is proposed that the plateau looked toward the north rather than the south and east.

Nonfigurative Representations

If the analysis of the subject matter shows that Siega Verde can be included within European Paleolithic art in general and is closely related to cave art in the Iberian Plateau, the study of the abstract representations leads to a different interpretation. It is well established that the appearance of complex abstract motifs is linked to spatial, chronological, and cultural criteria. The consideration of Paleolithic complex signs as ethnic markers (Leroi-Gourhan 1981) has been confirmed by several modern studies of the distribution of these signs. From this point of view, Siega Verde complies with the rule, as its abstract representations form an original system of their own.

Signs are quite scarce. Simple abstract forms predominate, especially incised lines which are mostly lesser artistic evidence. They may be

mere freestanding lines, or elements such as zigzags, comets, and other more elaborate forms, like the two crosshatches in the central sector. From this perspective, two types possess a greater significance due to their frequency and their preferences: circular and oval shapes and claviforms.

The former vary from ovals to open forms that tend toward an oblong shape. A total of 13 have been documented; they were mostly produced by pecking and their distribution is quite homogeneous. Pure circular forms are not found, as most of them are closed ovals, of which ten have been recorded. In general they only consist of the outline without any type of internal fill. Only on one occasion, in Panel 46, an oval shape has an internal vertical line that divides it into two, creating a shield-like figure. These are therefore very simple forms, which display spatial patterns and a general association with bovines.

The claviform signs are always pecked and consist of a vertical line with a lateral protuberance. In two cases this is in the upper third of the line, in six it is in the central part, and in four it is in the lower third. These signs resemble the Pyrenean and Cantabrian model in the late series, included in advanced early Style IV and the transition to the recent Style IV (González Sainz 1993: 45). This chronology seems too late for the representations at Siega Verde, whereas very old examples are known in Paleolithic cave art (Pike et al. 2012). A very early chronology is not incompatible with their persistence in time, even to the late limits that Leroi-Gourhan proposed, and surely not all the claviforms can be included in the same group. The cultural coherence in the classic Pyrenean-Cantabrian region allows this chronological coincidence, but the same cannot be affirmed for other regions (González Sainz 1993: 50). Morphologically they correspond to the late Pyrenean-Cantabrian model and not to the peculiar claviforms of the lower Magdalenian in northern Spain, but a series of thematic, stylistic, and compositional details suggest an older age. As in the case of the circular and oval shapes, the claviforms are associated with a certain animal, in this case the horses, in contrast with the model proposed by A. Leroi-Gourhan (1971).

The abstract inventory at Siega Verde can be defined as an ensemble of depictions in which most motifs are linear (claviforms, stripes) or are reduced to very simple shapes like ovals and circles. These abstract motifs form an original system of their own. There are no ogival or triangular forms as in the Central System mountain range nor any of the incised depictions such as tectiforms, scutiforms, scaleriforms, comets, straight or zigzagging lines, dots, and cupmarks as documented at Côa (Baptista 1999: 30, Table 4).

An autonomous catalogue of abstract forms was constructed on the banks of the River Agueda. Its difference from the group in the Central System mountain range may be due to geographic criteria, whereas the differences with Foz Côa may be because the two ensembles are of different chronologies (Alcolea and Balbín 2003: 250).

Style

Constant variation is seen between the large size of the pecked animals and the incised figures, which are always smaller and fit within the manual field of the artists. Thus the site displays a graphic selection equivalent to a hierarchic perspective, even though incision is suitable for drawing large figures, as can be observed in some stags in the central sector. The reason why bovines and horses are usually pecked must be connected with the difference between pecking and incision. Pecking is more visible whereas incision is more discreet, unless it is used as the basis for painting later.

At Siega Verde, the representations tend to be reduced to their outlines, with special emphasis on the area of their heads. There is a general lack of concern for the limbs, and the legs are omitted or represented with few details. Most animals are quite elongated, especially in the case of the large pecked figures. The level of details and artistic conventions is low and varies depending on the sector of the site. Most details are represented in the head (ears, eyes, and mouth) and are normally linear.

The spatial variation in the style is expressed by subtle changes. In the central sector the horses are represented with archaic internal dividing lines in the belly and have stepped or double manes that meet in an angle at the forehead and semicircular eyes next to the forehead. The aurochs are engraved with slender horns in correct or semi-twisted perspective and internal lines in their snout and eyes like those of the horses, while the cervids display internal lines in their neck and jaw. In the northern sector, the figures are smaller and better balanced, with more advanced internal lines, such as the "M"-shaped interior lines of the horses, while archaic features such as the stepped manes and eyes next to the forehead disappear almost absolutely.

Some animals seem to display more sophisticated conventions, although these are always associated with incision and smaller figures. This is the case of the ibex, where beards and tear ducts are represented. This may be the consequence of a different system, in which the details would be used to underscore the specific significance of the subject matter, as well as the greater capacity of incision to create minute details in the figures.

Most of the figures are represented in absolute profile, which derives from a tendency toward linear engravings, the lack of interest in the limbs, and the schematic nature of many of the horns, which do not correspond to the style of the rest of the body. The archaic nature of the disinterest in the limbs as well as such graphic procedures as the relatively poorly drawn "M"-shaped interior lines, the archaic details in the eyes and other parts, and the elongated form of many bodies seem to announce middle Magdalenian art without achieving it.

The articulation of the perspective with different parts of the body often results in figures drawn with at least two perspectives, even in a formula which combines absolute profile, horns in correct perspective, and limbs in twisted perspective, as in the large stag in the northern sector. The figures that combine absolute profile with straight biangular perspective are the most significant. Most of these are formed by animals with slender legs in a frontal view, but there are also bodies with horns in frontal view, like the "V"-shaped ears of several hinds and some horses. The frontal perspective of horns is the most frequent trait of both bovines and cervids in the central sector, while it is less abundant in the north, where figures in better accordance with visual reality were achieved.

Inanimate figures dominate in the ensemble, in line with the general simplicity of the figures. The omission of the limbs and the reduction of many figures to the area of the head explain this infrequency of animation, in addition to the fact that animated figures are very unusual in Paleolithic art.

In the few figures displaying animation, this is segmentary and limited to movements of a fore or hind leg, although a correct but partial depiction of movement is sometimes attempted, as in the case of the giant deer in Panel 13. Other examples are the bears at the site, which are represented with their paws in front of them and in a semi-erect position. In general, movement is always partial and inorganic, without truly achieving coordinated animation.

The least animated animals are the most numerous: the horses and bovines. Cervids are slightly animated and caprids more so. The felines and bears are most often shown in movement. It seems as if the large animals, the most numerous and dominant in the panels, were associated with static postures, whereas the less numerous compensated for their scarcity with animation.

As in other cases, the animation of figures appears to reflect certain stylistic evolution. The number of examples of animation appears to increase in the northern sector, normally in association with scenes.

A few figures with an archaic appearance are distributed across the site. These are some horses, bovines, and occasional examples of deer and ibex which must correspond to the non-evolved type at Foz Côa and other sites. They seem to be related to figures in caves in the Iberian Plateau, such as La Griega, Los Casares (in its oldest phase). and El Reno (also in its archaic phase), and are the only ones that link solidly with the iconography in the east and south of the Iberian Peninsula.

The other representations relate in a different way. Their correspondence with open-air sites like Domingo García, Mazouco, and Zézere is clear. However, even greater similarity is seen with caves in the Central and Iberian System mountain ranges. This is most apparent in the repetition of the treatment of equids and bovines, the dividing lines in horses' manes, and the modeling of the faces and chests of cervids. Additionally, another aspect affects some figures in the north of the site and has chronological implications: the presence of exotic animals in late phases.

Exotic animals and figures of anthropomorphs are of great importance in the stylistic and thematic analysis at Siega Verde. Woolly rhinoceros and felines also find their place in the Iberian Plateau. The case of the rhinoceros, which are unique in the Iberian Peninsula, apart from the example at Los Casares (Alcolea and Balbín 2003b: Fig. 16), repeats the situation of the reindeer and bison. At the same time as these animals appear in the north sector, more advanced graphic solutions are applied, as occurs in the caves in central Iberia. The indication of the coat on the pachyderms in Guadalajara and Salamanca is proof of this.

The felines at Siega Verde are quite schematic, partly because of the percussion method, but their presence on the plateau is well known, at Los Casares (Balbín and Alcolea 1992) and with greater doubts at La Griega (Corchón 1997: Table 1). They seem to be a motif characterizing the art of the plateau, especially as they are rare in northern Spain and limited almost exclusively to Tito Bustillo (Balbín et al. 2003: Fig. 58).

Bears are unusual in Iberian Paleolithic iconography. The figures at Siega Verde are similar to those at Tito Bustillo, and, together with the absence of these animals at sites in the south and east, this is another example of a relationship between Siega Verde and the north of the Iberian Peninsula.

Anthropomorphs are known on the plateau, where they form a large group throughout the Paleolithic (Alcolea and Balbín 2003: 227–228) and also in the north, whereas they are not found in the south or east. In addition to the well-known examples at Los Casares, figures have been documented at La Hoz (Alcolea and Balbín 2003: Figs. 5 to 8) and at La Griega, where two figures of this type have been recorded (Corchón 1997: Table 1). The figures at Ribeira de Piscos (Baptista 2001: Figs. 4 and 5) are of particular interest, as two incised anthropomorphs are very similar to the figures at Siega Verde. Their relationship is again mostly with northern Iberia.

It is clear that, within its originality, the subject matter at Siega Verde can be included within the model in the Castilian Plateau. The stylistic connections with the Mediterranean, if they were ever very significant, decrease with time, and only some archaic figures suggest a plausible relationship. The connections with northern Spain are more numerous and largely provide the foundations for the stylistic chronology.

Chronology

A debate about the Paleolithic age of the ensembles in the Douro Valley first arose in connection with the Côa sites. This debate, caused by a complex web of economic, political, and "scientific" interests, reached its peak with the reports issued by R. Bednarik (1995) and A. Watchman (1995). These reports mixed the results of attempts at direct and relative dating with contextual and stylistic arguments.

The results these studies reached, mainly by Bednarik (1995), suggested a Holocene age for the engravings at Côa. This was based on direct dates determined by micro-erosion, situated by Bednarik between 8500 and 6500 BP, and the minimum age of the engravings at Penascosa, calculated by the analysis of patinas to be 2703 BC and by TL/OSL to be about 4500 BP. These results were combined in Bednarik's study (1995) with a further three types of argument: the inexistence of cold species in the Portuguese ensembles, the absence of an archaeological context, and, finally, some stylistic traits of the figures that, in his opinion, were not characteristic of Paleolithic depictions. The same author produced a new study in 2009, but this time in reference to Siega Verde. Using similar arguments, he

proposed a sub-modern age for the engravings on the banks of the River Agueda (Bednarik 2009).

The opposite view was given by J. Zilhao (1995), who explained in detail all the methodological and interpretative errors committed by Bednarik. The Portuguese scholar criticized the use of experimental and unreliable dating methods and the profound ignorance of the archaeological context in inland Iberia. It may be added that the absence of extinct fauna is not a criterion to demonstrate the non-Pleistocene age of a rock art site. If it was, most of the cave sites accepted as Paleolithic would have to be rejected. The valid argument is completely the opposite; the presence of extinct fauna is a clear criterion to attribute a Paleolithic age to an artistic representation. In fact, Siega Verde contains several examples of extinct Quaternary fauna, which destroys the Australian author's first argument.

In second place, and following Bednarik's critique, it is not true that inland Iberian lacks Upper Paleolithic archaeological deposits. As J. Zilhao stated (1995: 114), late glacial occupations are known in the center of the plateau, as at La Dehesa (Fabián 1986), possibly corresponding to the late Magdalenian. Sites with pre-Solutrean and Solutrean occupations are also known, such as Peña Capón rock-shelter in Guadalajara (Alcolea et al. 1997a, b; Yravedra et al. 2016). Other sites in the north of the Douro Valley can be named, like Mucientes in Valladolid (Martín et al. 1986) and the caves of La Cantera and El Espertín in León (Neira et al. 2006). The latter sites seem to belong to an undefined period in the late Upper Paleolithic. The Magdalenian chronology and sequence at Estebanvela rock-shelter in Segovia (Cacho et al. 2012) can be added to the site already known at Verdelpino (Moure and López 1979) and the terraces in the surroundings of Madrid (Alcaraz et al. 2012). In recent years, a team from the University of Zaragoza has documented several Upper Paleolithic sites in the Ebro Valley, including Gato 2, Vergara/Alejandre, Bolichera, and Peña del Diablo, in the Jalón river valley, directly connecting with the plateau. This connection with the north and east of the Iberian Peninsula partly fills a gap in the area and once again demonstrates the existence of a Magdalenian occupation in the interior of the peninsula (Utrilla et al. 2006).

The main contradiction to Bednarik's argument is found in the Côa Valley itself, because the most important Upper Paleolithic remains in inland Iberia have been documented there. The centers that have been published to date are Quinta da Granja, Quinta da Barca, Quinta da Barca Sul, Salto do Boi, and Olga Grande (Aubry 2009). Salto do Boi possesses two archaeological areas, Cardina II and Cardina I. The first site seems to possess objects in a secondary position, probably from Cardina II, and levels 1–3 at Cardina I are attributable to the upper or final Magdalenian with a chronology of between 12,000 and 10,000 BP. Levels 4c–5 at Cardina CARDINA I belong to the final Gravettian and 4b to a pre-Solutrean level. These latter levels are dated to between 22,000 and 21,500 BP, a time that is well documented in the littoral region between the Tagus and the Mondego. Solutrean remains are also known, at the site of Olga Grande, and the levels superimposed archaeologically on the Gravettian engravings at Penascosa (Aubry 2009).

Excavations after 1999 at Fariseu, on the banks of the Côa, located occupation levels that covered a wall decorated with engravings that would have been produced before 18,400, by OSL/TTL dating, and until 11,000 BP. The style of these engravings corresponds to most of those in the archaic phase at Côa, and this find guaranteed the archaeological age of the whole open-air graphic ensemble (Aubry 2009), in opposition to the claims of some authors. Previously, in 1992 and 1995 (Balbín 1995; Balbín and Alcolea 1992), this chronological period had been proposed for the first engravings in the Douro Valley, based on stylistic procedures.

The open-air art on the Douro includes a first phase in Foz Côa, dated by stylistic elements and the archaeological context to A. Leroi-Gourhan's Style II. This characterization, already published elsewhere (Balbín and Alcolea 1992: 40), connects most of the Portuguese engravings with the oldest cave sites in the plateau: La Griega and El Reno.

A second phase of open-air engravings may be included in Leroi-Gourhan's Style III and early Style IV, in the Magdalenian. It is represented by the central sector at Siega Verde, Domingo García, and a few figures at Côa. Its cave version is abundant on the Iberian Plateau, with the same thematic and stylistic conditions: many of the figures at Los Casares and La Hoz, El Niño, El Turismo, and the late phase at El Reno Cave. The end of the sequence is found in the northern sector at Siega Verde, with the generalization of the most classic early Style IV traits ("M"-shaped internal lines, reduction in size of the figures, and animation), as well as frequent cold fauna (reindeer, woolly rhinoceros, bison). This phase is also found in the final figures at Los Casares and La Hoz.

This chronological assessment of the site of Siega Verde has been studied in several papers and most specifically in the monograph on the site (Alcolea and Balbín 2006: 305–328). The main arguments were the existence of Pleistocene fauna among the representations, the presence of sub-modern constructions covering decorated panels, and, above all, the superimposition of Paleolithic engravings over other prehistoric engravings of a different kind and style.

These engravings, whose chronology in the late Pleistocene and early Holocene has been argued elsewhere (Bueno et al. 2009), have been detected in other parts of the plateau, both in caves and in the open air, with the advantage that they have been documented archaeologically in the recent levels at Fariseu, dated in the tenth millennium cal BC, which in itself is an argument for a definitive relative chronology.

In order to define the position of Siega Verde in the chronological framework of the Upper Paleolithic, owing to the impossibility of using criteria of absolute and archaeological dating (Alcolea and Balbín 2006: 312), we have used indirect stylistic methods, to be precise the most convincing method, which is the one devised by A. Leroi-Gourhan (1971), despite the anti-stylistic reaction that has taken place in the last decade.

We have reflected on this issue elsewhere and proposed a positive and updated use of the methods of stylistic dating (Alcolea and Balbín 2007). This paper points out that absolute dates have partially ratified Leroi-Gourhan's system and that the problems of radiocarbon dating applied to rock art (few figures are dated, sampling errors, and significant proportion of incoherent dates) do not allow this to be a criterion that can replace stylistic and archaeological methods as a way to define the evolution of Paleolithic art.

The characteristics of most of the figures at Siega Verde indicate a middle phase that is neither very archaic nor very advanced within Paleolithic art. The general canon, characterized by certain dysfunction between the head and the body, which is often elongated, scarce details, lack of interest in the limbs, the rare animation, and the solution of perspective, with a predominance of absolute profile and infrequent uniangular perspective, fits within the scope of Leroi-Gourhan's Style III (1971: 252).

However, these characteristics are accompanied by others of a more advanced appearance: insistence on dividing lines in the belly, chest, face, and head and a gentler dorsal line, which is practically straight in most of the equids and cervids at the site. These traits imply that many of the figures must belong to later phases within Style III, when the depiction of internal dividing lines becomes widespread (Barandiaran 1972: 347), and which is also one of the periods best supported by direct dates.

The most significant sites in the plateau that can be associated with most of the figures at Siega Verde are the caves of Los Casares, La Hoz, and El Reno. The most reasonable chronology for Los Casares includes two phases, corresponding to late Style III and an initial early Style IV (Balbín and Alcolea 1992: 429). The cave of La Hoz seems to belong to a very similar decorative pattern, with one phase between the late Style III and the early Style IV and another one fully in early Style IV (Balbín et al. 1995: 44; Balbín and Alcolea 2002: 145–146). The generic similarity of Siega Verde with the late Style III figures in the caves is clear, whereas some figures in the northern sector on the River Agueda, such as the woolly rhinoceros and some horses with "M"-shaped dividing line, correspond well with the later phases at Los Casares, located in Chamber C and, above all, in Chamber A. Similarly, the diversification in the range of animals, the use of

natural rock forms to construct figures, and the general reduction in the size of the figures seen in the later phase at La Hoz repeat graphic behavior that is well represented in the north of Siega Verde.

The similarities with El Reno Cave are also significant. Like the others, this cave was decorated in two phases (Alcolea et al. 1997a: 255–256). In the first, painted and engraved objects with an archaic appearance can be dated between Styles II and III (Balbín and Alcolea 2002: 147), whereas the second, attributed to between Styles III and IV, repeats the traits seen at Siega Verde: horse's heads with a mane with a double angular line, archaic dividing lines in the chest and face of cervids, little attention to the limbs, etc. These examples, which can be completed with the similarities between the cervids and caprids in El Niño Cave and Siega Verde, suggest stylistic synchrony between the caves and the Agueda valley, which can be assigned to a time between Leroi-Gourhan's Styles III and IV.

This chronological proposal is ratified by considering analogies with northern Spain and especially with the caves in the Ramales de la Victoria group and La Pasiega Cave. The cervids at Siega Verde often display dividing lines in their chest and face that are very similar, although more simple, to the striated modeling of animals in Cantabria. As the figures in the north are initially attributed to the start of early Style IV, the examples at Siega Verde may be assigned to a slightly older phase, which underscores their correspondence to the transition between Leroi-Gourhan's Styles III and early IV.

The figures belonging to the oldest phase, principally two aurochs and some horses, found in isolation in several panels at the site, resemble figures in the ensembles at Côa, in La Griega Cave, and in the early phases in the caves in the Central System mountains, all thought to belong to pre-Magdalenian times, within Leroi-Gourhan's Styles II and III (Alcolea and Balbín 2006: 317). This date is supported by data from Fariseu in Côa (Aubry 2009), where a minimum age in the Solutrean or Gravettian has been demonstrated for engravings. This indicates that the intensive superimpositions in Côa correspond to a graphic resource rather than to a long chronology and suggests that most of the Quaternary cycle on the Portuguese river is dated in the Gravettian (Baptista and García 2002: 203–204). These figures may belong to an old phase which additionally signifies a connection between Siega Verde and Côa.

The site functioned during a relatively long period of time, which would correspond to the late Solutrean and first phases of the Magdalenian in northern Spain. In stylistic terms, the decoration was continuous, starting with forms that are characteristic of Styles II and III and then gradually advancing to the transition to the early Style IV and then fully in that style. The hypothesis might be proposed that most of the depictions were produced in a period of time between 18,000 and 15,000 BP. A smaller number of representations were produced before that time, while the upper limit would reach 14,000 BP, a time that corresponds to the middle Magdalenian in northern Spain (González Sainz 1989: 169, Fig. 59). Finally, some figures in the Paleolithic-Epipalaeolithic transition would be superimposed on these and form part of the so-called Style V in the Douro Valley.

Conclusion

Siega Verde is one of the most important rock art sites in the Iberian Peninsula and therefore in the whole of western Paleolithic art.

The study of the representations at Siega Verde has shown that the phenomenon of open-air rock art in inland Iberia is framed perfectly within known Paleolithic graphic activity in the area. The differences it displays with other sites, such as those in Côa, can be explained by its more recent chronology, which matches sites in the center of the Iberian Plateau, with which it displays undeniable connections. These circumstances signify that Siega Verde and thus the other open-air sites in Iberia do not belong to any exotic cycle different from that of the Paleolithic cave sites in Western Europe. Paleolithic rock art in the open air is situated in a different setting from that of the decorated caves, and this setting must have been commonplace in Upper Paleolithic graphic systems.

The mere existence of the sites in the Douro Valley, and their great similarity with the cave sites, implies that caves were just another setting for Paleolithic art and not the only one nor the fundamental one. Darkness and the mystery of the caves was not a determining factor in the graphic message.

Caves only provided the human groups with an ideal architecture in which to represent their discourse, an essentially linear architecture organized according to a unifying thread, which was formed precisely by the passages and chambers of the caves. The Rivers Agueda and Côa, with their river banks, provided a similar vehicle of communication for the inhabitants of the Douro Valley. They had no caves, but they possessed similar cultural and ideological concepts to those of other inhabitants of Europe in the last Ice Age.

The open-air sites in Iberia and the study of several classic cave ensembles underscore the urgent need to reappraise the meaning of European Paleolithic rock art. The principles that have been used uncritically are no longer valid and are unable to explain this rich and varied graphic world. More open and versatile explanations must be sought, to avoid resorting invariably to religion and hidden places as the only reasons for the development of Paleolithic art.

Sierra de San Francisco: Great Mural Rock Paintings

María de la Luz Gutiérrez Martínez
National Institute of Anthropology and History, La Paz, Baja California Sur, Mexico

Introduction

In the Baja California peninsula, Mexico, exists one of the most extraordinary repertoires of rock art in the country. This long and narrow strip of land sits between the calm, tepid waters of the California Gulf and the impetuous Pacific Ocean. In this peninsula rises an impressive series

Sierra de San Francisco: Great Mural Rock Paintings, Fig. 1 The central mountain ranges in Baja California peninsula: this is the distribution area of the Great Mural style

of mountain ranges that, along with the oceans that embrace it, provides interesting contrasts between the ocean, the desert, and the mountain. This landscape scenario provided optimal conditions for hunter-gatherer-fishing societies, who first inhabited the peninsula in the early Holocene, until the arrival of explorers and Jesuit missionaries at the end of the seventeenth century (Gutiérrez & Hyland 2002).

One of the most salient features of this region's prehistory is that its protagonists produced massive quantities of rock art since very ancient times. They found in the practice of painting and engraving an extremely important medium of ritualistic expression and in the resulting rock art an extraordinary instrument of communication. In this way, the symbolism expressed in the imagery can be considered an essential element in the process of construction and consolidation of the social identities of these peoples through the millennia.

The central mountain ranges of the peninsula represent the densest concentration of rock art (Fig. 1). In these mountains, the imagery is persistently integrated with the landscape, symbolically inscribed, and it gives it a cultural meaning that shows us with clarity the fluid movement of the peoples who created it, witnesses and protagonists of the comings and goings (Conkey 1984: 264–267; Gutiérrez and Hyland 2002: 30).

Key Issues/Current Debates/Future Directions/Examples

The Rock Art Tradition of Great Murals

The Great Mural style (Gran Mural) is one of the most prominent of the region. This term was coined by Harry Crosby (1997) in the seventies taking into account their large size. The Sierra de San Francisco is the one that concentrates the

most spectaculars Great Mural sites. The paintings are located in hundreds of rockshelters in the intermountain canyons. The style is essentially realistic and is dominated by human figures and animals painted in red, black, white, and yellow. In 1992, these rock paintings were inscribed in the UNESCO World Heritage List.

On the rock panels of the Sierra de San Francisco, the anthropomorphs are static or unmoving, while the posture of some animals suggests certain movement. The female figures can be identified by the breasts that are positioned under the arm as well as by the demonstration of pregnancy (Fig. 2). The animal that appears most frequently is the deer, followed by the Bighorn Sheep, but there also exists a broad range of land and marine animals depicted (Fig. 3).

Chronology and Cultural Affiliation

One of the key questions surrounding the archaeological investigation of the Great Murals concerns their antiquity. The first references to the murals can be found in the records of the Jesuit missionaries of the eighteenth century (Barco 1973). The impression given by some of these records was that the paintings were "old," while the indigenous people denied knowledge of their origins, attributing them to the work of an ancient and lost race of giants from the North.

Before 2000, there were only six radiocarbon dates for three panels of the Great Murals (Fullola et al. 1994; Gutiérrez and Hyland 2002: 337). There has been a more recent focus on increasing the chronological information about this pictorial tradition. From the radiocarbon dates that have been obtained so far, one stands out. The panel of Cueva San Borjitas has a date as far back as 7500 B.P. (which signifies Before Present) (Watchman et al. 2002). The investigations surrounding chronology have produced interesting debates but also valuable information about the production process of the paintings and the meaning behind their creation.

Another essential aspect has been to verify the origin of the pigments and explore the possibility of identifying the minerals. The analyses indicate that the paint is composed of local mineral pigments: red and yellow from iron oxides, black from manganese oxide, and white from gypsum. Large deposits of gypsum and of red iron oxide, intense in color, quality, and varying shades, can be found in the Azufre Canyon, in the Volcanes Tres Vírgenes (Three Virgins Volcanoes) (Fig. 4). Archaeological evidence tells us that this source was used to obtain the pigments. It should be noted that this paint recipe was formulated not only for creating the rock art imagery but also for the development of body painting (Gutiérrez and Hyland 2002; Gutiérrez 2009).

Sierra de San Francisco: Great Mural Rock Paintings, Fig. 2 Cueva del Batequi, Sierra de San Francisco. The female image is identifiable on the basis of her breasts and probable pregnancy

Sierra de San Francisco: Great Mural Rock Paintings, Fig. 3 It is common to find maritime animals in some Great Mural sites. To the *left*, the sea lion-whale of site San Gregorio II and to the *right*, hare and stingrays in site Cuesta de San Pablo

It is interesting to note that as the Great Mural panels are located further away from this source, decreases the intensity of the color in the rock paintings and many of them were only outlines. This may correspond with the difficulty that faced the most distant groups to travel to the volcano and collect the precious pigment and could explain the changes in the chromatic component of the southern substyles. A hypothetical explanation is that the volcano could have been perceived as the dwelling of mythical beings, bearers of unusual properties like the pigments and obsidian; in these terms, the pigment could have been considered rare, and the distant groups would have had limited access to them and thus had to use them in moderation.

Context and Function

In general the panels of the Great Murals present a complex diversity of style, theme, and archaeological context, showing us of the plurality of its origin and function. The presences of human figures or wounded animals have led many researchers to suggest that the painters reproduced scenes or hunting and/or combat, while others describe the shamanistic orientation of the imagery.

Another perspective has been to contextualize the paintings based on the religious concepts and ritualistic practices of the peninsula (Gutiérrez and Hyland 2002). The veneration of the ancestors and of the dead shaped the nucleus of the indigenous worldview around which developed a set of ritual practices; among these practices stand out the communication with such entities through its embodiment, and the spirit possession under a state of trance. The layers of human hair, the wooden effigies, the tables and ceremonial sticks, and the rock art, were elements of the ritual paraphernalia and served as substitute images of mythological heroes and remote ancestors.

The importance and intensity that had image production for the representation of the dead and ancestors, is the key to understanding the meaning and role that played some emblematic panels of Great Mural, those that are characterized by their huge dimensions and by the predominance of

Sierra de San Francisco: Great Mural Rock Paintings, Fig. 4 Extensive pigment deposits found at Cañón del Azufre in Tres Vírgenes Volcanoes. To the *left*, the end of this canyon and Sierra de San Francisco on the back and to the *right*, pigment deposits

Sierra de San Francisco: Great Mural Rock Paintings, Fig. 5 Cuesta Palmarito, Sierra de San Francisco. This Great Mural panel is characterized by the human figures with a wide range of headresses and chromatic patterning

human figures, which showing a broad range of headdresses and colored patterns (Fig. 5). Detailed analysis shows that certain figures were repainted, possibly throughout centuries. What motivated this "reactivation" of the images? It is possible that the personages painted in these sites could represent founding ancestors of lineages and/or mythical beings; in this sense, the groups of images concentrated the collective memory of these groups, and, through the ritual of repainting, the people worshipped them, reaffirming at the same time their individual and group identities.

The functions of the rock paintings and the sites that contain them could have been numerous. By analyzing each of the categories of identified panels, we would be in a position to deepen the study around origin, function, and rhythms of the creation of the imagery, the places that contain them, and the resulting symbolic space. Meanwhile, what we can confirm from a general perspective is that the role that the Great Murals played as a codifying system of visual communication was very successful, because their consistency, expands propagation and the permanency of certain emblematic images tells us of the great ability that its makers had in the construction and consolidation of this landscape and the capacity of the society to decode their meaning, on more than one level, throughout the history of the region, and over vast territories of local and regional identities, pervaded with memory and feeling.

Silbury Hill: Environmental Archaeology

Gill Campbell and Matthew Canti
Historic England, Fort Cumberland, Eastney, UK

Introduction

Silbury Hill in Wiltshire, UK (NGR SU 100 685), is the largest prehistoric mound in Western Europe. Its lies at approximately 158 m OD close to the source of the river Kennet, on the western side of the valley bottom within a natural amphitheater formed by the surrounding chalk hills. It is one of the complexes of early prehistoric monuments that comprise the UNESCO Avebury and Stonehenge World Heritage Site with Avebury Henge lying 1 km further up the valley to

Silbury Hill: Environmental Archaeology, Fig. 1 Silbury Hill is in the top left of the picture. The village of Avebury (lying partly within the Avebury Henge) is seen in the foreground (©English Heritage)

the north (Fig. 1), the West Kennet palisade enclosures 1 km to the east, and the West Kennet chambered long barrow occupying the first chalk ridge to the south east. Silbury Hill is a designated scheduled monument (National Heritage List for England 1008445; Scheduled Monument 21707; formerly County Number WI 2SAM 220743) and also a site of special scientific interest (SSSI) on account of the rare chalk grassland vegetation that grows on its slopes. The site is under the guardianship of the Secretary of State for the Department of Culture, Media and Sport and is managed by English Heritage on the UK government's behalf (Whittle 1997; Field and Leary 2014).

Today, Silbury Hill takes the form of a flat-topped cone 150 m in diameter and just under 31 m high when measured from the original land surface (37 m when the depth of the large external ditch surrounding the mound is taken into account). The mound itself is the result of multiple phases of activity and sits on a truncated old land surface (see below). At the center is a low gravel mound (maximum height 0.8 m, diameter 10 m) over which is a mixture of topsoil and turves, enlarging the central mound to just over 1 m in height with an estimated diameter of 22 m. A series of wooden stakes (recorded as stake holes) around the edge of this lower organic

Silbury Hill: Environmental Archaeology, Fig. 2 Section through Silbury Hill showing the different phases of construction (Eddie Lyons ©English Heritage)

mound may have held the structure in place but could equally have been freestanding. Also believed to belong to this phase of activity are one or more smaller additional deposits (mini-mounds) constructed around the central mound, again comprising turf and topsoil. Following on from this phase, pits were dug into the surface of the organic central mound, rapidly backfilled with turf and topsoil then built up, resulting in a central mound of some 35 m in diameter. This upper organic mound was additionally sealed by a series of further dumped layers made up principally of chalk and silty clay, around which at least five chalk and clay banks were constructed, gradually increasing the mound's size. Many of these banks may be associated with the cutting and recutting of a large ditch dug some 50 m out from the center of the hill. However, the first phase of the ditch is associated with a separate bank thrown up toward the center of the hill (i.e., on the internal side), suggesting that the mound may have, at one time, sat inside an enclosure with an internal bank. The later phases of the hill are less well understood because of the nature of the archaeological interventions (see below) but the deliberate backfilling of the ditch, followed by a series of recuts each slightly further out from the center of the mound, possibly continued until the final form of the ditch surrounding the hill was achieved. Similarly, while the piling of quarried chalk was used to expand the monument above and around the central mound and the surrounding deposits, at some stage a different procedure was adopted which entailed the construction of revetment walls of chalk rubble, behind which fine chalk dumps were built up. It is this technique which is evident from excavations on the summit of the hill (Leary 2014; Fig. 2).

The whole construction process is likely to have lasted somewhere between 55 and 155 years. The lower organic central mound and additional mound(s) are estimated to have been completed between 2460 and 2395 cal BCE with final completion estimated at between 2335 and 2270 cal BCE (Marshall et al. 2014). The building of the hill thus falls within the same time period as major constructions at Stonehenge and Avebury.

Definition

The importance of Silbury Hill to environmental archaeology lies in the wealth of biological remains preserved within the organic mounds

and representing the early phases of the monument's construction. As the macroscopic plant remains, mollusks, and insects are derived from the turf and topsoil incorporated into the organic mounds (and from materials laid down or surviving within the old land surface beneath the hill), they give a unique insight into the nature of the late Neolithic environment within an area of major monuments. The remains are preserved due to the anoxic nature of the deposits within the center of the hill. These preservation conditions result from a combination of reduction and limited gaseous exchange between the deposits in the center of the mound and the outside air caused by the sheer volume of the hill coupled with the results of the extra compression caused by "the enormous weight of the mound" (Evans 1972: 267; Canti et al. 2004; and the entry on "▶ Environmental Archaeological Evidence: Preservation" in this encyclopedia).

In addition to the delicate biological remains, two other areas of interest from Silbury are the nature of the old land surface and the use of antler as tools. Antler picks are one of the main cultural materials recovered from late Neolithic deposits at the site which generally produced very little cultural material, animal bone, or charred plant remains. This paucity of finds suggests that the site may have been deliberately kept clean (Campbell 2014; Leary and Field 2014).

Historical Background

There have been four major archaeological interventions into the center of Silbury Hill (Fig. 3). The first comprised the digging of a vertical shaft from the summit down to the center of the hill, carried out by Colonel Drax and the Duke of Northumberland in 1776. The aim of this endeavor was to recover the burial believed to lie under the center, but all that was recovered from the base of the shaft was single sliver of oak (Whittle 1997: 9–10; Leary and Field 2010). The second excavations took place in 1849 funded by the Archaeological Institute. A horizontal tunnel was dug into the center of the hill from the southwest side of the mound with further tunnel extensions excavated in the center. While this excavation also failed to find a central burial, it was the first to record the extraordinary preservation of biological remains deep within the hill. The Very Reverend J. Merewether, in his account of the 1849 excavations, notes both the freshness of the moss found on turves piled up in the center of the hill and also the presence of mollusks, beetles, and other plant remains (Merewether 1851).

The huge potential of the environmental material only began to be realized following the next major intervention between 1968 and 1970 which was sponsored by the British Broadcasting Corporation (B.B.C.) and directed by Prof. R Atkinson. The tunneling works partly incorporated the footprint of the 1849 tunnels but extended further and included the excavation of two lateral tunnels to the east and west. Among the principal aims of this excavation was to gain an understanding of the composition and date of the monument and "to document its environmental setting" in the light of Merewether's findings (Whittle 1997: 11). To this end, a suite of pioneering environmental analyses was carried out on materials recovered from the tunnels including studies on soils, pollen, macroscopic plant remains (including mosses), insects, mollusks, and vertebrate remains (see Cornwall et al.; Dimbleby et al., respectively, in Whittle 1997). While these analyses are a major source of information concerning the site, they suffer from a lack of information about where exactly the material came from, and it is not always possible to ascertain whether the assemblages were recovered from the old land surface or from one of the organic mounds, additional mounds, etc. Thus, while the results give a good overall picture, indicating the presence of open herb-rich grazed grassland in the immediate vicinity of the hill in the later Neolithic (Whittle 1997: 140), details concerning the nature of the old land surface and the different deposits making up the mound are lacking (Canti et al. 2004; Campbell 2014).

The fourth major and most recent archaeological investigation at the site occurred during 2007–2008. The research took place as part of a

Silbury Hill: Environmental Archaeology, Fig. 3 Plan of Silbury Hill showing the 1776, 1849, and 1968–1970 interventions. The 2007–2008 remedial works reused the 1968–1970 tunnels from Leary et al. in press. (Eddie Lyons ©English Heritage)

major conservation project by English Heritage involving remedial works to the hill. These works were carried out in response to the discovery of voids resulting from incomplete backfilling associated with the 1776 shaft, the 1849 tunnel, and the 1968–1970 tunnels. It was clear that the voids would continue to migrate up through the hill to eventually be expressed on the surface, disrupting irreplaceable archaeology: a problem first brought to light by the sudden appearance of a hole on the summit of Silbury Hill on the 29 May 2000, caused by the collapse of the deposits in the 1776 shaft. Thus, the decision was made to re-excavate the 1968–1970 tunnels and to directly

backfill all the voids in order to conserve the monument and prevent further damage to its archaeology. This work was accompanied by detailed archaeological recording, including extensive sampling of in situ and disturbed deposits encountered in the sides of the tunnels in order to recover artifacts and biological remains and for geoarchaeological analysis. The results of this work are detailed in Leary et al. (2014). Some of the key findings from the environmental archaeology are discussed below.

Key Issues

The Nature of the Old Land Surface

Silbury Hill is situated on a 1–2-m deep layer of clay-with-flints drift overlying solid chalk, so the preconstruction surface of the chalk spur would have had a clay-with-flints soil profile over much of its area. Inside the hill, the old land surface was characterized by a relatively stone-free dense gray silty clay loam or silt loam layer formed at the junction between the chalk overburden and the underlying clay-with-flints. The layer was as little as 3 cm thick in some places (Fig. 4) but tended to gradually thicken downhill (toward the center of the mound) and was as much as 10-cm thick at some points. It mostly had a smooth interface with the chalk above it but also sometimes showed irregular upper surfaces (Fig. 4b).

The gray clay layer often had a sharp boundary to the underlying clay-with-flints, usually including a marked gravelly band. Variants on this basic morphology were found in the main exposures to the south and in the lateral tunnels. Toward the center of the hill, the gray layer was less pronounced and showed more gradual changes with depth. Comparisons with local soils on clay-with-flints showed clearly that, even allowing for redox-based color changes, a simple compression (as would occur if the hill was built straight onto the topsoil) could not generate the thin examples of the dense gray layer (Canti et al. in press).

The gray layer and underlying clay-with-flints were characterized using particle size analysis. This showed a strong relationship between the two materials. Although there was a wide variation among the samples, the gray layer could, essentially, be derived from the clay-with-flints if most of the stones larger than 2 mm were removed and the clay content was reduced by 10%.

Processes to effect this sorting were considered (including trampling and erosion), and some experimentation was carried out to try and simulate it. In the end, earthworm casting was thought to be the only feasible possibility. Earthworm action is capable of deep sorting (see, e.g., Canti 2003, Fig. 7), and the Silbury soil represents a fairly intense example. Although the process is commonly associated with more calcareous soils than those found on clay-with-flints, the unusual

Silbury Hill: Environmental Archaeology, Fig. 4 (**a**) Typical example of the thin gray layer overlying clay-with-flints that forms the old land surface beneath the hill. (**b**) Irregular upper surfaces of the layer overlying clay-with-flints. (Matt Canti ©English Heritage)

lowland position of the Silbury deposit and possible calcareous inputs from upslope would likely overcome any inhibition due to acidity.

The Silbury builders would, therefore, have found a well-developed worm-sorted topsoil on the chalk spur and deturfed it. They cut well above the stone layer in many cases, producing the old land surface examples with a deeper gray clay layer. Toward the south, perhaps stimulated by increasing distance from the turf stack, they tended to go deeper and arrived at just 2 or 3 cm above the stone layer, producing the profiles seen in Fig. 4. The grayness of the gray layer would arise from leaching of the iron compounds chemically reduced (and thus rendered soluble) by decay of the organic matter still left in the earthworm casts.

The Biological Remains from the Organic Mounds and the Nature of the Later Neolithic Environment of Silbury Hill

Turves that can be cut as soil blocks and used in construction only form under open vegetation types such as grassland, moorland, and heaths. This is because, in order for the turf to hold together, there has to be dense vegetation cover and a mat of roots such that the topsoil remains attached to the surface vegetation (Hall 2003; Campbell 2014). It is therefore not unexpected that the majority of the biological remains recovered from the organic mounds within Silbury Hill attest to open grassland habitats. However, there is considerable variation between different turf samples and different contexts. This partly results from the nature of the matrix making up the different mounds.

The central lower organic mound is principally composed of turves and topsoil formed on neutral to acidic clay-with-flints material, resulting in pollen being relatively well preserved. In contrast, the upper organic mound contains typically rendzina turves and calcium-rich topsoil, leading to excellent preservation of mollusks but the destruction of pollen evidence. Overall, macroscopic plant remains and insects are preserved well in both mounds (see "▶ Environmental Archaeological Evidence: Preservation"). There is also a wide range of preservation states between different specimens, because some material was living or fresh when incorporated (e.g., moss growing on the surface, seeds forming part of the soil seed bank, and whole beetles (Fig. 5)), whereas other material was either dead or decayed when incorporated (e.g., dead grass, fragmented beetle remains, worn mollusk shells, and partly decayed seeds). These complex taphonomic factors impose limitations on interpretation but also present opportunities. Thus, the month in which a given turf was cut cannot be determined from the presence of the wings of the queen ant *Myrmica sabuleti* since these wings are bitten off following mating flights and would be plentiful around any ant nests, surviving in the soil for some time (Robinson 1997: 41, 43; Robinson in Campbell 2014). On the other hand, the presence of worn mollusk shells of species typical of woodland along with poorly preserved seeds of

Silbury Hill: Environmental Archaeology, Fig. 5 Mangold flea beetle (*Chaetocnema concinna*) found squashed on the surface of one of the turves, scale bar 2.5 mm. (Gill Campbell ©English Heritage)

woodland plants such as *Mercurialis perennis* (dog's mercury) and *Rosa*/*Rubus* type (rose or bramble) thorns among well-preserved remains of mollusks indicating dry open grassland and well-preserved remains of *Ranunculus* cf. *bulbosus* (bulbous buttercup) within an individual turf can be used to reconstruct the history of the turf; it may have been cut from grassland developed following woodland clearance undertaken probably less than a century earlier (Campbell 2014).

Bearing these factors in mind, the results from samples of individual turves from the central organic mounds within Silbury Hill indicate that turves were cut from grassland developed on at least two contrasting soil types, with different land-use histories and subject to varying degrees of wetness, disturbance, and grazing pressure. The moss remains in particular allow aspect (whether the turf was cut from a north- or south-facing slope) to be postulated (Williams 1976; Hall and Campbell 2014), while the presence of *Lasius flavus* gp. ants which build ant hills in old grassland may suggest the harvesting of turves from mature grassland (Robinson in Campbell 2014).

The results from the only mini-mound to be sampled gave somewhat different results than those of the central organic mound. Although a grassland element is present, indicators of woodland environments including propagules of *Taxus baccata* (yew), *Prunus spinosa* (sloe), and *Ajuga reptans* (bugle) along with some woodland beetles and well-preserved specimens of shade-loving mollusks such as *Clausilia bidentata* (common door snail) were recorded. Some cereal remains were also recovered, which given the evidence for animal dung obtained from the insect remains could be derived from the droppings of livestock fed on cereal chaff. At the same time, the few water beetles identified from this deposit (*Colymbetes fuscus*, *Helophorus* cf. *brevipalpis*, and *Hydrobius fuscipes*) which was otherwise largely devoid of wetland species suggest the presence of temporary pools or puddles. Overall, these results give an impression that the material used to construct this mound may have been gleaned from the woodland edge, where cattle or other livestock sheltered, churning up the ground to create muddy pools (Campbell 2014).

The contrasting environments represented in the materials used up to make the different organic mounds could all have been found within the immediate vicinity of the site, though this does not mean that elements could not have been brought from within the wider area of the Marlborough Downs. Indeed, the fact that different habitats were incorporated into different areas of the hill might be taken as evidence that the inclusion of different parts of the landscape into the monument held significance for those building the monument, as has been suggested for the inclusion of sarsens in the upper organic mound and for the monument as a whole (Leary and Field 2014; Leary and Field 2010: 119–122).

However, probably more important from an environmental perspective is the clear evidence for the existence of a herb-rich chalk pasture in the environs of Silbury in second half of the third millennium BCE. This is indicated by the presence of plants such as *Sanguisorba minor* ssp. *minor* (salad burnet) and *Linum catharticum* (fairy flax, and *Scabiosa columbaria* (small scabious), all of which were recorded both as plant macrofossils and during the first surveys of the vegetation growing on the monument in the mid-nineteenth century (Buckman 1864–1866; Williams in Whttle 1997; Campbell 2014). In addition, the numbers and percentage of remains of scarabaeoid dung beetles and meadowland weevils that feed mainly on grassland leguminous plants indicate grazing by domestic animals with stocking levels similar to those found in the area today (Campbell 2014; Robinson 1997). This implies careful management of the environment by late Neolithic people with grazing rights controlled or negotiated within or between groups (Campbell 2014).

International Perspectives

The biological remains from Silbury Hill give very little evidence of human occupation, in contrast to sites such as early Neolithic La Draga (see this encyclopedia "► La Draga: Environmental

Archaeology"). Rather, the site provides a snapshot of a late Neolithic landscape with clear evidence for the managed grazing of livestock and the presence of herb-rich chalk grassland. The fact that some of the turves from the organic mounds contain evidence of past woodland strongly suggests that if grazing ceased or was reduced, much of the area would eventually revert to woodland. Indeed, where indicators of woodland were recorded, the taxa found are more typical of secondary rather than primary woodland. These results fit in with the regional picture. Some clearance of primary woodland is attested from the beginning of the fourth millennium cal BCE followed by increased human presence and further clearance. The end of the fourth/beginning of the third millennium cal BCE appears to have been marked by woodland regeneration with the advent of Silbury coming at the same time as evidence for renewed clearance (Whittle 1997: 140; Campbell 2014). The presence of a generally wooded environment in the earlier Neolithic in the Avebury region contrasts with that for other areas of the southern chalk which seem to have been more open with larger areas, of grassland. Furthermore, it is suggested that, in these areas, post-glacial woodland may never have become fully developed and it is no longer valid always to assume that, prior to human influence, a given site would have been wooded (Allen and Gardiner 2009).

Analyses of biological remains present within turves (sods) used in the construction of mounds and other structures have been carried out at a number of other sites and provide valuable information on land-use history and the nature of the environment (Hall 2003; Karg 2008). Recent work on macroscopic plant remains in close conjunction with the geoarchaeological analysis of individual turves used in the construction of the Skelhøjthe mound, near Ribe, Denmark, has provided evidence of the management of heathland vegetation for grazing at around 1350 cal. B.C. The turves from beneath the iron pan layer represent the first meter of the mound makeup and contained well-preserved plant and insect remains preserved as a result of anoxic conditions. *Calluna vulgaris* (heather) remains, including roots, stalks flowers, and seeds, formed the principal component of the surface vegetation on the turves along with other species indicative of dry grazed heathland. Within the turves charred remains of heather and other plants such as *Rumex acetosella* (sheep's sorrel), *Pimpinella saxifraga* (burnt saxifrage), and *Carex pilulifera* (pill sedge) showed that the heathland had been previously burnt with the age of the heather and the nature of the surface vegetation, suggesting that this probably occurred between 3 and 10 years prior to the turves being harvested. The regular burning of heath increases fertility, prevents scrub encroachment, and ensures that heather flourishes at the expense of other species. Young plants and shoots of heather are also more nutritious than older growth. The results from the Skelhøj mound show that this traditional method of managing heath for grazing was already practiced in the fourteenth century cal B.C. (Karg 2008).

Future Directions

Green "Grass" Remains

The reported evidence of "short grass with square ends" from within Silbury Hill (Whittle 1997: 140) along with descriptions of the vegetation retaining its green color (see, e.g., Whittle 1997: 16) is one of the unusual features of the remains from this site. Pieces of green plant material were also recovered during the 2007/2008 excavations at Silbury, and the majority of these remains appeared at low magnification to resemble fragments of grass leaves or stems with some showing squared ends. However, when investigated further using transmission electron microscopy (TEM), this material was found to lack cellular structure consisting only of two thin outer membranes containing portions of chloroplast thylakoid membranes within an amorphous matrix (Collinson et al. 2011; Fig. 6).

In order to determine what this material might be and to understand how its unusual preservation might have arisen, it was compared to a number of different modern plant derivatives including fresh, rotted, animal digested, and humanly processed

Silbury Hill: Environmental Archaeology, Fig. 6 (**a**) Silbury green plant material as it appears in situ as thin strands with blue green to bottle green color, scale bar 300 µm (Margaret Collinson and Eddie Lyons, ©English Heritage) (**b**) Green plant material in TEM section, scale bar 1 µm. (Margaret Collinson, Tony Brain and Eddie Lyons, ©English Heritage)

material using TEM. Of the plant materials examined, partially fermented (couched) woad (*Isatis tinctoria*) most closely resembled the green plant material from Silbury Hill as all the others retained cellular structure. While it is not proposed that woad is present at Silbury, the results suggest that the green plant material consists of partially fermented higher plant tissue (further determination is not possible given the lack of diagnostic features). This fermentation may have occurred naturally during construction, but it is also possible that the green plant material was the waste product from some unknown process involving fermentation, with the by-product being placed or discarded into the mound. Further work is required involving the examination of experimentally fermented plant material from known species, as well as material cut, trampled, and then treated in a variety of different ways (Collinson et al. 2011, Collinson et al. in Campbell 2014).

Antler

The 2007/2008 excavations at Silbury Hill produced a small fragmented antler assemblage probably resulting from the use of antler picks as tools, though only five antler fragments showed wear that could not be attributed to deer behavior. In addition, a chalk block bearing strike marks from an antler pick was recovered during excavations on the summit. There are also a number of other finds of antler from the previous interventions, with these finds often referred to as deer horn in the early reports (Worley 2014).

It is postulated that an antler pick can only be used as a tool for a single day during which time it can be used to dig out around 3 m^3 of chalk. Given that the volume of chalk making up Silbury Hill is estimated as somewhere between 236,000 m^3 and 23,900 m^3, this would mean that over 78,000 picks would have been needed over the period of construction (see above), so something like 500 antler picks would be needed each year. While these figures only provide estimates, they do serve to illustrate that the collection of shed antler would have been an important spring activity for people at this time and that in all likelihood this commodity would have been traded or exchanged as a valuable resource. Antler could also have been harvested from deer killed for meat (Worley 2014).

The small number of fragments retrieved from the various excavations into Silbury Hill, even taking into account the tiny proportion of the mound that has been excavated, suggests that the majority of tools or broken tools were not discarded on site. This could relate to the need to keep the site "clean" (see above) but might also mean that even broken fragments were reused or recycled into other items. This pattern of disposal might further indicate that those antler fragments that were found within the hill represent deliberately placed deposits. Similar practices have been noted at other ceremonial sites. The central zones of such sites (e.g., Avebury, Durrington Walls) tend to be free from antler tools, whereas caches of antler picks have been recovered from their ditches where they are interpreted as offerings marking the completion of works (Worley 2014).

The question of how and from where the antler picks used to build Silbury Hill were procured has become the subject of new research, funded by a grant from the British Academy. This project aims to discover whether strontium isotope analysis can be used on the antler from Silbury Hill to determine its provenance. If successful, the method could be applied to other sites and other antler artifacts.

Silverman, Helaine

Helaine Silverman
Department of Anthropology, University of Illinois at Urbana-Champaign, Urbana, IL, USA

Basic Biographical Information

Helaine Silverman received her B.A. at Queens College of the City University of New York, M.A. at Columbia University, and Ph.D. at the University of Texas at Austin. She holds the position of full professor in the Department of Anthropology at the University of Illinois in Urbana-Champaign where she is also the director of the university's Collaborative for Cultural Heritage Management and Policy (CHAMP). Prior to becoming involved in cultural heritage research, Dr. Silverman conducted many years of archaeological fieldwork on the south coast of Peru.

Major Accomplishments

Dr. Silverman's Nasca research in the 1980s and 1990s rewrote understanding of this ancient society, which previously had been known almost exclusively on the basis of its exquisite polychrome pottery and the countless tombs from which this material had been looted over the course of almost a century. She overturned the dogma that early Nasca had been organized as a state and that Cahuachi, the greatest early Nasca site, had been a city. Her fieldwork at Cahuachi and in several valleys of the Río Grande de Nazca drainage proved the lack of political centralization in early Nasca society and that Cahuachi had functioned, basically, as an "empty ceremonial center" animated by pilgrimage but without significant residential population. She also was the first scholar to contextualize the "mysterious" Nazca Lines (geoglyphs) within the society that produced them, identifying scores of geoglyph sites of various types on the hillsides of the valleys where the Nasca population lived and demonstrating the relationship between habitation sites and geoglyphs.

In addition to her own publications, Dr. Silverman has been a prolific editor of influential volumes on Andean archaeology: *Andean Archaeology* (Blackwell, 2004) and with William H. Isbell, *Andean Archaeology I: Variations in Sociopolitical Organization* (Plenum/Kluwer, 2002); *Andean Archaeology II: Art, Landscape, and Society* (Plenum/Kluwer, 2002); and *Andean Archaeology III: North and South* (Springer, 2006). She and Isbell also coedited the massive *Handbook of South American Archaeology* (Springer, 2008), a state-of-the-art compendium and the first to tackle the continent since Julian H. Steward's *Handbook of South American Indians* in the late 1940s.

It was constant media attention to her Nasca investigations that led Dr. Silverman into the cultural heritage field. She became intrigued with public interest in the past and how the past was deployed by the tourism industry and constructed by the Peruvian nation-state. As part of this new work, she also conducted ethnoarchaeological work on modern Peruvian cemeteries and in museums.

Dr. Silverman's current research is a critical analysis of the cooperative and conflictual production of archaeological monuments as cultural heritage sites for visual, performative, economic, and political consumption as undertaken by national governments, regional authorities, local administrations, community stakeholders, and the global tourism industry. In this regard, she has been conducting a long-term study of the historic district of Cuzco, former capital of the Inca Empire and today one of Peru's foremost tourist attractions. She also has worked in Thailand where has been studying the impact of cultural tourism in Phimai, a small town in whose center towers a great ancient Khmer temple that is currently on the Tentative List and intended for inscription on UNESCO's World Heritage List.

Dr. Silverman is a member of Forum-UNESCO, an expert member of ICOMOS' International Scientific Committee on Archaeological Heritage Management (ICAHM), and an affiliate member of ICOMOS's International Scientific Committee on Cultural Tourism (ICTC). She serves on the editorial boards of *International Journal of Heritage Studies, Heritage & Society, American Anthropologist* and *World Art*. She is a former editor of *Latin American Antiquity* (2008–2010). She was the book series editor for "Critical Perspectives in Identity, Memory and the Built Environment" (Routledge) and currently edits the "Heritage, Tourism, and Community" book series (Left Coast Press) and coedits ICAHM's book series, "Multidisciplinary Perspectives in Archaeological Heritage Management" (Springer).

Singapore: Cultural Heritage Management

Southeast Asian Studies Programme, National University of Singapore/Nalanda-Sriwijaya Centre, Institute of Southeast Asian Studies, Singapore, Singapore

Introduction

Singapore is a small, densely populated country. Five million people live on the main island, which covers about 650 km^2. Competition for land is intense. These considerations are often cited to explain the fact that Singapore is one of the few countries in the world where archaeological resources are not protected by law. There is no official archaeological department; archaeological research in this country has been mainly funded by donations from private sources, with some government grants for specific projects. Research has been conducted by university academics from the National University of Singapore and Nanyang Technological University, students, and unpaid volunteers.

Several official bodies have duties concerned with specific aspects of heritage conservation; these include the National Heritage Board, the Urban Redevelopment Authority, and the Preservation of Monuments Board. The National Heritage Board, and the National Museum which forms part of it, has contributed funds and some administrative assistance to archaeological research projects. Other funds have come from NGOs (the Lee Foundation and the Southeast Asian Ceramic Society) and corporations (Royal Dutch Shell, American Express).

In 2010, the Institute of Southeast Asian Studies established an Archaeology Unit under its Nalanda-Sriwijaya Centre. The Unit conducts research in Singapore and elsewhere in Southeast Asia. The National Parks Board has allocated funds for the construction of an outdoor display on an archaeological site in Fort Canning Park. This is one of Singapore's most important precolonial sites and provides visitors with an opportunity to see a display of artifacts and a preserved example of stratigraphy. The Singapore Heritage Society is a registered nongovernmental organization, and often speaks out on issues of heritage management. The Society publishes books on the subject, and comments on topics of concern to the local media.

Definition

In this entry, the term "cultural resources" is understood to mean all artifacts and man-made structures of the period before 1950, and all sites where concentrations of such artifacts can be found, whether in disturbed or undisturbed contexts. "Management" will be used to refer to efforts by official bodies to preserve or modify these artifacts and sites.

Key Issues

The Singapore government has exhibited a laissez-faire attitude toward its archaeological heritage. Excavations since 1984 have demonstrated that sites exist with artifacts dating from the early fourteenth century, with some objects (Chinese coins) brought to the island at that time actually dating back to the Tang Dynasty (618–906). These sites consist of a fourteenth-century elite residential/craft zone on a hill now known as Fort Canning, and a settlement of artisans and traders on the left bank of the Singapore River which was occupied from the early

fourteenth to the early sixteenth centuries. The government has sponsored archaeological research at these sites, one of which has been preserved and presented to the public as a semi-permanent display. However, the government has not adopted proposed legislation which would have required contractors to stop work in case of the discovery of potential archaeological sites within the boundaries of the fourteenth-century urban area. There is no requirement that any impact assessments be conducted in advance of construction projects.

Conservation of individual buildings began in the 1970s when the Urban Redevelopment Authority (URA) and Preservation of Monuments Board (PMB) were formed. Controversies arose in the 1980s regarding the URA's focus on preserving individual building facades while neglecting districts and street life. The URA's policies have evolved as a result.

History of Archaeology in Singapore

Archaeological research in Singapore dates from January 1984, when the Singapore National Museum organized a test excavation at Fort Canning, a park where the museum staff suspected artifacts representing precolonial occupation might be discovered. The project succeeded in uncovering evidence of fourteenth-century occupation. In 1987, the Department of History of the National University of Singapore hired a lecturer to teach courses on archaeology and ancient history; the Parks and Recreation Department, the body which was then in charge of developing the park in which the archaeological site was discovered in 1984, hired the lecturer as a part-time archaeological consultant.

An excavation in 1987 was conducted as part of a sequence of archaeological workshops sponsored by the Association of Southeast Asian Nations (ASEAN). A total of 12 excavation projects has been carried out in Fort Canning Park, built on Fort Canning Hill (Miksic 1985, 2006). The name is derived from a British fort built on the top of the 45-m-high hill in 1859, then largely demolished in 1928 to build a reservoir. Other military structures were built on the hill's lower slopes at the same time.

The Fort Canning office of the Parks and Recreation Department (since 1990 the National Parks Board, NParks for short) has been very supportive of archaeological research. Although there is no requirement to do so, the management of Fort Canning Park often contacts an archaeologist when they discover remains during their normal maintenance activities, and when sizeable earth-moving is contemplated. For example, when handicapped access facilities are installed, they notify the archaeologist so that the location affected can be studied.

Public Archaeology on Fort Canning

In the 1990s, a number of projects were carried out to exploit the historical and cultural resources of the park. These include the redevelopment of a semi-historical, semireligious Muslim shrine called the Keramat Iskandar Shah; the construction of two Walks of History (one with signboards related to the fourteenth century and the other commemorating important sites of the British colonial period which began in 1819); and the development of a permanent display at a part of the archaeological excavation which revealed fourteenth-century artifacts in their original contexts.

The first project to be completed was the redevelopment of the Keramat, in 1990. In 1822, the jungle on the hill's surface was cut down and a number of brick ruins were found on the hill. According to a contemporary description (Crawfurd 1967 [1828]), these ruins were made of good quality brick, and were sufficiently numerous that they covered the greater part of the slope. Among the ruins were scattered Chinese and local pottery and Chinese coins dating from the Tang and Song Dynasties. A tradition rapidly arose, on what grounds it is not known, that the site was the final resting place of Iskandar Shah, the founder of the kingdom of Malacca and one of the first Malay rulers to accept Islam. According to Chinese sources, he died around CE 1413. A series of new structures were built on the site by devotees upon its discovery. By the 1980s, nothing of the original structure remained.

NParks formulated plans to build a new structure on the site, to call attention to the historical

Singapore: Cultural Heritage Management, Fig. 1 Keramat Iskandar Shah

character of the park. The few details noted in Crawfurd's description given just after the site's rediscovery in 1822, together with motifs used for early wood-carving, were combined to create the structure seen there now. A carved stone plaque records what is known of the history of the site and Iskandar Shah. It is one of the main stops on the fourteenth-century Walk of History. These walks are simple in concept: paths, in most cases preexisting, with appropriate plaques set up in suitable locations giving information about the historical significance of the site (Fig. 1).

The next major development was the erection of a roof with similar design to that over the Keramat to protect a partially completed excavation where dense evidence of fourteenth-century activities has been recovered. Dr. John Chen Seow Phun, Minister of State for Ministry of National Development and Ministry of Communications and Information Technology, officially opened the facility on 20 April 2001. Visitors can view an actual excavation which presents a soil profile with an early twentieth-century brick foundation in the top layer, beneath which is a layer of sterile red laterite soil, which changes at a sharply defined boundary to a dark brown loam containing a dense concentration of fourteenth-century artifacts. Around the pit, which measures 100 m^2, is a walkway with captions providing information on the general history of fourteenth-century Singapore, and explanations of general archaeological methods. Within an adjoining gallery are cases containing samples of artifacts excavated from the site, together with posters identifying the artifacts discovered and the methods used to recover and interpret them (Fig. 2).

NParks also conducts archaeology-themed events. These involve families who are given a chance to carry out mock excavations in sand boxes, using genuine artifacts found in the hill, and visiting the archaeological site near the Keramat.

Also in the early twenty-first century, reconstructed versions of colonial-period features were erected at the south end of the park. These include a flagstaff, lighthouse, and time ball. These are principal features of the nineteenth-century Walk of History. Further enhancements include installation of a sequence of carved cement reliefs depicting imaginary scenes from Singapore's history along the staircase at the south slope of the hill.

Eleven structures from the British colonial period still stand on Fort Canning. These include six military structures: the main fort gate and a sally port, built in 1859, and the Underground Command Centre and three other military buildings dating from 1928. The other remaining features from the colonial period are part of Singapore's first cemetery, which was in use from 1822 to 1860; they include two gothic

Singapore: Cultural Heritage Management, Fig. 2 Archaeological display, Fort Canning Park

Singapore: Cultural Heritage Management, Fig. 3 Gateway to Fort Canning Cemetery, 1848

gateways built in 1846 (Fig. 3), a monument to the son of a prominent British resident of the colony who died in 1848, and two cupolas built as places for cemetery visitors to rest. These cemetery features have been well preserved, whereas the tombstones which once crowded the graveyard were removed in the 1960s and set into the brick wall surrounding the cemetery.

In 1992, the role of Fort Canning in World War II was commemorated by a short-term exhibition held in the Underground Command Centre, a very large command bunker. Public response to the short-term exhibition was so strong that it was decided to make plans for a permanent exhibition in the bunker. NParks leased the bunker to a private firm for development: a bidder who won the right to develop another major British military structure on the hill into a country club. The structure had been the headquarters of the British high command in World War II, where Lieutenant General A.E. Percival, the General Officer Commanding Malaya, had his office.

The redeveloped bunker opened on 15 February 1997 (the 55th anniversary of the fall of Singapore to Japanese forces). The presentation utilizes techniques such as elaborate

technology for simulating a bombing attack, narration broadcast over a local FM transmitter to which visitors listen through headsets, and animated wax figures of soldiers. The installation of these displays required the remodeling of the structure including the drilling of new doorways through walls and excavation of floors to facilitate the flow of visitors and installation of simulators. Displays were fabricated using surplus military equipment purchased in Britain, of types which were not used in Singapore. Mock-ups of some rooms were given functions used in other rooms; for example, the Fortress Plotting Room became the Gun Operations Room, while the real Gun Ops Room is used for the bombing simulation. Most of the original fabric and atmosphere have thus been lost (Fig. 4).

Other Archaeological Sites in Singapore

In 1993, a reconnaissance of a site designated for Singapore's new Parliament House Complex yielded evidence that an archaeological record of precolonial activity was preserved there. In 1995, an archaeological team was given 2 months at the beginning of the rainy season when no construction could take place to attempt to recover more data on early Singapore. This was later extended by another month.

The site occupied a location on the north bank of the Singapore River in a position which seemed likely to have been occupied by residents of the ancient Temasik mentioned in Chinese, Javanese, and Vietnamese sources in addition to Malay texts. Excavations there demonstrated that the site contained undisturbed fourteenth century remains.

Since 1995, ten other sites in Singapore have been excavated, some in order to recover more evidence of the fourteenth century, others to explore the material culture of nineteenth and early twentieth-century Singapore. Artifacts from these research projects are now on display in the National Museum, the Asian Civilisations Museum, St. Andrew's Cathedral, and the National University of Singapore Museum. Most of the artifacts were stored in the Fort Canning Centre, a building on Fort Canning belonging to the National Parks Board, until 2008, when they were moved to the campus of the National University of Singapore, where cataloging and analysis are conducted by students and volunteers.

Other Singaporean Institutions Involved with CRM

In 2010, the Institute of Southeast Asian Studies announced the foundation of an Archaeology Unit under the Nalanda-Sriwijaya Centre. This unit

Singapore: Cultural Heritage Management, Fig. 4 Interior of Underground Command Centre before restoration

was officially launched in August 2011. The Unit has no jurisdiction over archaeological resources; it will still have to seek permission to conduct research from the landowner. The Archaeology Unit works closely with the archaeological laboratory which was set up at the National University of Singapore in 2009. The university has not courses on archaeology, but a course on CRM in Southeast Asia has been taught annually since 1999. Several academic exercises and master's theses have been written for the Department of Southeast Asian Studies, which was founded in 1991 as a program, and became a department in 2011.

The National Museum of Singapore has passed through a number of phases since Singapore became an independent nation in 1965, after having formed part of Malaysia for 3 years, and a British colony since 1819. The museum's building was erected in 1887, and for the next 75 years, it amassed a collection of specimens of flora, fauna, and ethnographia, with a few archaeological remains, from the Malay Peninsula and neighboring areas. The new nation was content to leave the museum mainly as it was inherited until 1984, whereupon the museum's potential as a nation-building tool was acknowledged, and major renovations were instituted (Kwa in press).

In 1994, the works of art and the artifacts from other parts of Southeast Asia were removed from the National Museum's collection and divided among a new Singapore Art Museum and an Asian Civilisations Museum. In 2006, a new wing was added to the old National Museum, and an archaeological gallery was installed. This gallery has a permanent exhibition of artifacts from systematic excavations in Singapore, and an audiovisual presentation in a theater which lasts about 12 min. This presentation is unusually designed, because instead of providing one standard narrative, it compares the interpretation of precolonial sources on the basis of different sources (Malay, Chinese, Javanese, and Portuguese).

In 1995, a Chinese Heritage Centre was founded; it is housed at the Nanyang Technological University. It focuses on the recent history of the overseas Chinese and has no archaeological interest. In 2000, preparatory to the development of a Malay Heritage Centre in a nineteenth-century palace, the Istana Kampung Gelam, archaeological excavations were conducted in the Center's courtyard. Excellent results were obtained in the form of different types of artifacts representing life in the palace in the nineteenth and early twentieth centuries, a period for which very little written documentation exists. A small sample of these was exhibited in the Centre until 2010, when they were removed as part of a major renovation of the Centre. It is not known whether they will be reinstalled in future. They are now stored in the archaeological laboratory of the National University of Singapore (Fig. 5).

Singapore: Cultural Heritage Management, Fig. 5 Istana Kampung Gelam excavation

An Indian Heritage Centre is the next such institution to be constructed. Plans have been made for a 3-week excavation at the site selected for the Centre in March 2012. If artifacts are found, they will be exhibited in the Centre together with artifacts of Indian origin found in fourteenth-century contexts elsewhere in Singapore.

Archaeology is gradually becoming recognized as a part of the Singapore story. One of the ways in which this field may make a deeper impression is connected with an online 3-D multi-player role-playing game entitled World of Temasek (www.worldoftemasek.com). This game was developed by the Media Development Authority of Singapore, the National Heritage Board, and an IT company, Magma Studios, and launched by the Minister for Information, Communications and the Arts, Lui Tuck Yew, on 3 March 2011. The game allows players to put themselves in the position of a character such as a spice trader, a pirate, or a sailor in Temasek (the fourteenth-century name of the island). Illustrations in the game are taken from archaeological data, and levels of information and interpretation available in the game provide illustrations of artifacts, links to historical sources, and other materials.

The Urban Redevelopment Authority and the Preservation of Monuments Board are other governmental institutions with jurisdiction over cultural resources. These resources are defined in terms of buildings, either individually or in streets or districts. Their involvement in archaeology has been minimal, but these two bodies have developed an increasingly sophisticated strategy aimed at preserving examples of colonial period architecture and districts. The Singapore Heritage Society, an NGO, has often lent its support to archaeological projects and preservationist causes.

Sion, Petit-Chasseur (Neolithic–Bronze Age): Geography and Culture

Jocelyne Desideri
Laboratory of Prehistoric Archaeology and Anthropology, Department F.-A. Forel for environmental and aquatic sciences, University of Geneva, Geneva, Switzerland

Introduction

The canton of Valais contains one of the most important Swiss Neolithic sites: Petit-Chasseur in Sion. While this site is already internationally renowned for its megalithic necropolis dating from the Late Neolithic to the Early Bronze Age as well as for its beautiful anthropomorphic stelae, it also has occupation levels dating to the Middle Neolithic and burial sites of the Second Iron Age. The site of Petit-Chasseur was discovered in 1961, following the work of civil engineers in the heart of the city of Sion. It was extensively excavated by O. J. Bocksberger from 1961 to 1969 and by A. Gallay from 1971 to 1973. New interventions were carried out in 1987–1988 by S. Favre and M. Mottet, in 1992 by M. Besse, and in 2003 by M. Mottet.

Definition

Levels of Habitat in the Middle Neolithic

The Middle Neolithic occupations at Petit-Chasseur are subdivided into three phases (Besse and Piguet 2011). An early occupation phase dating to 4,500 BCE, and attributed to the Middle Neolithic I, was very poorly preserved, and no housing plan can be reproduced. A middle phase, situated between 4,000 and 3,800 BCE, attributed to the Middle Neolithic II – Cortaillod of the Petit-Chasseur type – reveals the best-preserved habitat. At this level, a hamlet composed of at least three housing buildings and a construction interpreted as a space dedicated to penning livestock have been identified (Fig. 1). Finally the third phase, dating from 3,800 to 3,600 BCE, is associated with the Middle Neolithic II – Cortaillod of the Saint-Léonard type. This level presents at least two domestic units, but these are poorly preserved, preventing identification of the housing plans.

The homogeneity and the distribution of the remains found are in line with similar ways of life and similar choices of consumer products (Besse and Piguet 2011). Production activities were oriented toward goat breeding and cultivation of cereals (barley and wheat). Subsistence activities and crafts were controlled at the scale of the house. Diverse and varied influences are highlighted by the study of ceramics. The lithic industry was dominated by quartz used for domestic blade production. During the regional Middle Neolithic in general, the knapping of quartz took place off-site, near the sources (Besse and Piguet 2011).

Excavations in the Middle Neolithic II habitation levels also revealed seven funerary structures (Besse and Piguet 2011). These are cysts of *Chamblandes* type, burial vaults formed of four slabs in a pit and, in general, a capstone. The chamber is covered with materials from the pit. Each cyst contains one or more individuals, usually buried in left lateral or supine position, with limbs bent. In domestic context, burials of this *Chamblandes* type contain mainly for juveniles (Desideri and Besse 2009).

Sion, Petit-Chasseur (Neolithic–Bronze Age): Geography and Culture, Fig. 1 The structures of the stratigraphic series of Middle Neolithic II, Cortaillod type Petit-Chasseur and the supposed boundaries of the buildings (Besse and Piguet 2011: 64)

The Megalithic Necropolis of Petit-Chasseur

The famous megalithic necropolis of Petit-Chasseur reveals an occupation that lasted for nearly fifteenth centuries. The magnificent collection of anthropomorphic stelae and funerary objects could be correlated to different chronological phases, thus enabling a seriation of several construction stages and use of the 12 monuments – MI to MXIII – of the megalithic area, from the Late Neolithic to the Early Bronze Age (Fig. 2).

Funerary Occupation During the Late Neolithic

The necropolis includes two monuments dating from the Late Neolithic, collective graves MVI and MXII. These are dolmens with a triangular base and antennas.

Dolmen MXII is the oldest megalithic area monument from Petit-Chasseur (Favre and Mottet 2011). It shows an occupation that lasted between five and seven centuries from 3,100 to 2,400 BCE and is the only tomb containing human remains in place for this period. The first phase of burials was completely reworked, and the remains piled northwest of the burial site. The second phase begins with the burial of an individual – in the middle position in the grave – in a slightly lateral right position. Next, those buried were spread in successive layers composed of three lines of two bodies, generally laid in supine or lateral position with limbs bent. Before a new occupation, a regular reorganization took place by leveling the ground and removing the bones disturbing the leveling. The skulls were moved and stored against a slab of the monument. The burial chamber contains at least 115 individuals.

Dolmen MVI, meanwhile, reflects a more diverse history spanning about eight centuries, from the Late Neolithic to the Bell Beaker or from 3,000 to 2,200 BCE (Bocksberger 1976). This monument was erected after dolmen MXII.

Sion, Petit-Chasseur (Neolithic–Bronze Age): Geography and Culture, Fig. 2 Map of the megalithic necropolis of Petit-Chasseur (dolmen MXII and cyst MXIII located 100 m from the other monuments not shown) (Favre et al. 1986, plate 1)

Three separate moments can be distinguished. The first occupation is Late Neolithic and corresponds to the initial phase of construction use, although information regarding the original position of those buried in the monuments is difficult to precisely determine. This difficulty is linked to the second occupation phase, because the Bell Beakers emptied the burial chamber. However, it was possible to inventory 33 individuals from the first occupation (Gallay 1986).

Funerary Occupation During the Bell Beaker Period

Within the megalithic necropolis of Petit-Chasseur, the Bell Beakers display both mixed and new behaviors, mixed because they both reused earlier monuments and built their own monuments (dolmens and cysts) and new because although the construction of cysts is known in the Bell Beaker cultural area, the construction of collective monuments remains an original behavior (Besse and Desideri 2005).

The Bell Beaker occupation begins with the construction of three dolmens at the side entry (Gallay 1986). Dolmen MI contains no bones, but the remains of five individuals were found outside of the building with Bell Beaker artifacts. Dolmen MV contains the remains of nine individuals. Dolmen MXI contains at least 15 individuals. A reconstruction of the position of those buried inside the monuments was not possible.

Later, the Bell Beakers removed the remains of the first occupation phase (Late Neolithic) from dolmen MVI and laid them outside the monument (Bocksberger 1978). While the skulls were given special treatment – they were found carefully aligned along the wall of the dolmen – the rest of the bones and associated material were thrown in a jumble. It is likely that the evacuation was carried out in a single event, since no refitting between bones inside the room and those outside could be done. The Bell Beakers thus had a new place to put their own graves. The contents of the inside of the monument were completely disturbed, which does not seem to be related to a single moment, but rather to ongoing and repeated Bell Beaker visits to the grave. There are 14 individuals (Gallay 1986).

Finally, the Bell Beakers built new small graves around ancient monuments, that is, cysts MII, MIII, MVII, MVIII, MIX, MX, and MXIII (Gallay 1986). Some of these did not contain bones, but others contained from one to seven individuals.

Anthropomorphic Stelae

Thirty-one anthropomorphic stelae were recovered in the megalithic necropolis of Petit-Chasseur. Two types of stelae – A and B – were identified, respectively, attributed to the Late Neolithic and Bell Beaker. The stelae were all found in secondary position, being reused in the construction of monuments or simply lying flat next to the graves (Corboud and Curdy 2009).

The stelae of type A present sketchy anthropomorphic elements (limited to the drawing of arms, forearms bent at right angles, and opposing hands) and horizontal bands suggesting belts, double spiral pendants, daggers, and axes (Fig. 3).

The stelae of type B are lavishly decorated with weapons in their sheaths, clothes represented by geometric designs (tunics, loincloths, belts, bags, etc.). The appearance of the bow with a strap worn

Sion, Petit-Chasseur (Neolithic–Bronze Age): Geography and Culture, Fig. 3 Stela 24 of type A in reuse in the construction of dolmen MXI: height 193 cm, width 94 cm, 10–11 cm thick (Favre et al. 1986, plate 20)

Sion, Petit-Chasseur (Neolithic–Bronze Age): Geography and Culture, Fig. 4 Stela 25 of type B in reuse in the construction of dolmen MXI: height 157 cm, width 86 cm, 10–11 cm thick (Favre et al. 1986, plate 21)

over the shoulder with one or more arrows can also be seen. Type B stelae can be separated into masculine and feminine stelae, the latter characterized by the absence of weapons (Fig. 4).

These stelae have been interpreted as representations of important people in the community rather than deities. Their discovery in secondary position, notably reused as raw material in the construction of funerary monuments, suggests a change in status and above all a loss in symbolic value associated with either social death (during one's lifetime or at death) or the natural death of the important person it represented (Gallay 2009).

Funerary Occupation During the Early Bronze Age

The latter occupation phase of the megalithic area of the Petit-Chasseur is attributed to the Early Bronze Age (Gallay 1986), during which we see the appearance of individual tombs. Earlier graves were pillaged and emptied, the human bones regrouped and incinerated. A female individual is buried in dolmen MXI, some juveniles were placed either inside old emptied tombs (MV) or outside in the adventitious cysts (MVI and MXI). Finally, several burial tombs were also recovered in which the bodies were placed to lie on slabs (Bocksberger 1978).

Burials of the Second Iron Age

The site of Petit-Chasseur also contains seven individual burials dating to the La Tène period (Curdy et al. 2009). The entire funerary during the Iron Age is not yet known, and the tombs discovered demonstrate a relatively wide dispersal. The orientation of the graves is constant (NE/SW), and the dead are in supine position, with the head facing NE. The bodies appear to have been placed in wooden containers (dugouts [*monoxyles*] or planks). Funerary objects are abundant and include ceramics, swords, shield knobs, fibulae, and other ornaments.

Key Issues/Current Debates/Future Directions/Examples

The cultural sequence of Petit-Chasseur is one of the most comprehensive in the alpine area. The exceptional quality of the recovered archaeological remains and the system of field documentation make this site a key reference in understanding the history of Neolithic populations, not only in the Alps but also at a European scale.

The year 2011 marked the 50th anniversary of the discovery of Petit-Chasseur. It is clear that this group has been and still is the source of dozens of university theses (masters and doctorates) and a number of significant monographs, the results of successful collaboration between the three institutions responsible for its promotion (the Cantonal Service of Archaeology in Valais, the cantonal museums of Valais, and the Laboratory of Prehistoric Archaeology and Anthropology – formerly the Department of Anthropology and Ecology – at the University of Geneva).

Site and Artifact Preservation: Natural and Cultural Formation Processes

Margaret Beck
Department of Anthropology, University of Iowa, Iowa City, IA, USA

Introduction

One of the best-known archaeological sites in the world is Pompeii, a Roman town buried by the eruption of Mount Vesuvius in CE 79. The disaster stopped daily life in its tracks, felling residents who were unable to escape and covering everything with a thick layer of ash. Millions of modern tourists visit Pompeii each year, now able to walk its streets, inspect its art (and graffiti), and peer into shops and homes. The casual observer might therefore imagine that *most* places of past human activity remain as they were in use, perhaps simply buried under a thick layer of dirt or volcanic ash. In this view, an archaeological site – much like the abandoned home described by Philip Larkin in his poem "Home Is So Sad" – "stays as it was left/Shaped to the comfort of the last to go."

Of course, nothing stays exactly as it was left. All archaeological sites suffer the effects of time,

climate, and organisms (including people). Organic materials at Pompeii that were not burnt subsequently decayed. Remains of the unfortunate residents trapped in the town decayed and could only be reconstructed by pouring plaster into the voids in the ash left by their bodies. Some of those who escaped later attempted to salvage what they could find and remove it from the site. After the rediscovery of the site, the material record at Pompeii was heavily affected by both looting and archaeological investigation.

Looting, decay, disturbance, and other natural and cultural processes affect the archaeological record (Schiffer 1987 for the best overview). These processes do not render it meaningless, but they must be recognized so that we can consider their impact on our sample of sites and artifacts, spatial patterning, and other matters so crucial for interpretation (see also ▶ Bam: Archaeological and Social Investigations After the Earthquake).

Key Issues/Current Debates/Future Directions/Examples

Natural Processes of Decay (and Preservation in Different Environments)

Some materials survive the vagaries of time better than others (Sease 1994 for an overview). *Highly perishable organic materials* include skin and soft tissue as well as wood and other plant remains. In most cases, these are very vulnerable to decay and hence do not survive in the archaeological record except under unusual conditions. As a result, at most sites we are unlikely to find baskets, textiles, wooden artifacts, leather, and any remains of people or animals other than bones or teeth.

The exceptions generally occur in arid, frozen, or waterlogged environments, such as deserts, glaciers, and peat bogs, which prevent decomposition and are favorable for preservation. Famous examples of organic preservation come from desert sites such as White Dog Cave (a Basketmaker site in northern Arizona), with conditions that naturally mummified burials, and Cahuachi (a Nazca site in coastal Peru), with cotton and wool textiles; the frozen body of the "Iceman" in the Italian Alps; the waterlogged site of Ozette in Washington state, United States, with wooden houses and artifacts; and peat bogs, including sites from northwestern Europe with Iron Age "bog bodies." Burial by volcanic ash may also seal the environment and prevent decomposition, such as in some contexts at the Cerén site in El Salvador. Decomposition may also be retarded by associated materials; copper, salt, or oil around organic items has been observed to preserve the organic remains.

Organic materials may also be preserved through burning. Charcoal (carbonized wood) and other carbonized plant remains are crucial sources of information about diet and other plant uses. Whole loaves of bread have been recovered from Pompeii because they were completely carbonized and therefore could not decay. Carbonized organic material preserves well in a variety of environments, but it is physically fragile. *Less perishable organic materials* include bone, ivory, and teeth, all of which have both a calcium-rich mineral component and an organic component. (We may also include shell here because it is made of calcium carbonate, although shell has no organic component and does not decay.) All of these materials preserve best in soils with neutral or slightly alkaline pH, as acidic environments break down the calcium-rich mineral component. For example, almost no bone was preserved at the Sloan site, a cemetery in the southeastern United States dating to around 10,000 years ago on acidic terrain. As a result, burial locations could only be inferred through calcium concentrations (into which the bone had disintegrated) and artifact clusters. Bones are also damaged and altered during processing and consumption of the carcass. Damage from human butchery provides important cultural information, but it may also result from carnivore and scavenger activity (Binford 1987).

Nonorganic materials include ceramic, glass, metal, and stone artifacts. Porosity is one factor affecting the survival of these materials, because greater porosity increases vulnerability to wet-dry cycles, freeze-thaw cycles, and accumulation of salts in the burial environment – all of which will lead to periodic expansion and stresses within the

body of the piece. For ceramics, firing temperature and temper type can significantly affect porosity and other attributes related to survival. Fiber-tempered pottery, which is the earliest pottery used in North America, is especially vulnerable to freeze-thaw action because of its high porosity. Calcareous temper, such as shell or limestone, will dissolve in acidic environments, leaving voids in the fabric. Such environments also cause acid leaching, or leaching of iron, lightening the color of the ceramic (Rye 1981).

The survival of glass and metal depends considerably upon its composition as well as the burial environment. Acidic soils are favorable for glass, but alkaline soils will cause leaching of the glass matrix. Pure gold resists corrosion from moisture and oxygen, but other metals (including those added to gold as part of the alloy) do not. Iron corrodes easily, producing reddish rust. Copper corrosion leads to a variety of colors, including green, and the chlorides in saline soils dramatically speed copper corrosion.

Stone generally survives well, but as with other material types, the structure and porosity is important. Mica, with its many thin sheets, is especially fragile physically. Limestone will erode or dissolve in acidic environments, as do other calcareous materials; this soft and porous rock may also suffer from erosion from wind, water, and crystallization of salts. Some combination of these factors probably caused the damage visible on the famous limestone monumental sculpture in Egypt, the Great Sphinx of Giza. Salts are of special concern in arid regions, because if not removed, they may continue to damage artifacts, even during curation (Fig. 1).

Site and Artifact Preservation: Natural and Cultural Formation Processes, Fig. 1 Damage from accumulated salts in (**a**) a prehistoric Hohokam effigy vessel from Arizona and (**b**) a modern flowerpot from Arizona. The modern flowerpot displays active growth of salt crystals (Photos taken by the author)

Natural Processes That Move and Damage Artifacts

Natural processes and their effects on archaeological sites are often addressed by the field of geoarchaeology (e.g., Goldberg and Macphail 2006). Natural processes can move artifacts and disturb features, sometimes so much so that the archaeological site is no longer a "primary" site (where the cultural deposition originally occurred) but a "secondary" site (where materials were redeposited). The effects of gravity seem obvious, for example – materials on slopes often move downhill – but materials deposited on level ground may also move around, up, and down. All of the processes that deposit, remove, and churn soils and sediments also affect soil within that matrix. Such processes include deposition and erosion from wind and water as well as the movement of particles by animals (faunalturbation; Fig. 2), plants (floralturbation; Fig. 3), freeze-thaw action (cryoturbation), and the shrinking and swelling of clay (argilliturbation).

Changes in climate also change the natural processes operating in a given place, altering conditions of preservation and threatening some archaeological sites that were not previously at risk. This is particularly evident in regions with melting glaciers or permafrost as well as in coastal

areas subject to flooding given higher sea levels. Warmer temperatures in the twenty-first century have thawed previously frozen Scythian tombs in Siberia, exposed Thule sites on Greenland's coast to greater erosion from storm surges, and flooded present and past areas of human occupation in Oceania. In the USA, the National Park Service is partnering with Native American communities and university researchers to study, predict, and mitigate the effects of climate change on cultural resources in the national parks.

Cultural Processes of Site Destruction: Scavenging, Looting, and Site Reuse

People frequently interact with material left by past activities, changing the nature of the evidence archaeologists will find. They may remove or alter traces of human behavior, soon after or long after the fact. This happens in a wide variety of ways at all stages of archaeological site formation, often motivated by a desire for the objects previously deposited or for the space these deposits occupy.

The process of reclaiming discarded or abandoned artifacts happens all the time in all societies, although it plays out differently in rich industrialized nations than in poorer ones. In the United States, the regular discard of usable, edible materials directly into the trash has spawned an entire movement known as "freeganism," in which adherents feed, dress, and entertain themselves from garbage deposits to protest against rampant consumerism and reduce environmental impact. In contrast, rural villagers such as Maya groups in Guatemala and the Kalinga of northern Luzon, Philippines, extensively reuse and recycle items before sending unusable scraps to a midden.

But these middens too may subsequently be modified: many are close to paths and activity areas, and may be dispersed by human and animal foot traffic at least along the margins. Children also collect things from middens for their play, and animals wander in to eat vegetable matter left over from food processing (Fig. 4). If trash deposits start to interfere with village needs (e.g., if they become too large or too smelly, or if they sit on land now desired for another purpose), they will be moved.

Abandoned residential sites may have more to offer in terms of reuse. Building materials are routinely scavenged from old dwellings for the new ones, either in the same community or a nearby one. If a dwelling or community was abandoned quickly or destroyed catastrophically, residents might have been forced to leave many items there, materials worth scavenging later. Some discarded items prove to be useful later for new reasons; for example, Hopi potters in the US Southwest are among those known to collect both sherds and pots to serve as models for designs and to grind up as temper.

Site and Artifact Preservation: Natural and Cultural Formation Processes, Fig. 4 Disturbance of a modern village midden by domestic animals in northern Luzon, Philippines (Photo taken by the author)

Some collectors are looking for wealth, things of beauty, or souvenirs, and this type of collection – like other processes of cultural disturbance – happened thousands of years ago just as it does today. The tombs of Egyptian pharaohs were targeted by robbers long before excavators such as *Belzoni* arrived in the early nineteenth century. Early visitors to archaeological sites often brought a shovel for souvenirs, a pattern common to many places including the eighteenth-century Spanish *presidio* in Tucson, Arizona, and nineteenth-century ghost towns in the western USA. Once materials have spent a certain amount of time in the archaeological record, many modern societies now have laws regulating their collection, although these laws are not always adequately policed. The illicit trade in antiquities continues, linking looters who dig up the items for sale to the museums who buy them (Watson and Todeschini 2007).

Archaeological sites are frequently reoccupied, reused, or affected by redevelopment and renewal. The buildings so hauntingly documented in Marchand and Meffre's *The Ruins of Detroit* will not simply dissolve in place to form Detroit's archaeological record; this is a living city, and the structures will eventually be rehabilitated, replaced, or removed. Boston's Central Artery/Tunnel Project or the "Big Dig" of the late twentieth century, while rerouting Interstate 93, displaced existing structures in use and also encountered abundant archaeological deposits. In the mid-twentieth century, Tucson, Arizona, demolished portions of the city from the nineteenth century, including the Spanish Convento and San Agustín chapel as well as its Chinatown, to make way for a convention center. Needs and values concerning the past change over time, and communities sometimes regret such land-use decisions. In awareness of the potential losses, the *Cultural Heritage Management* profession works to record significant sites before they are altered or destroyed and to mitigate the loss of information.

Conclusions

All archaeological sites have been altered in some way since their creation. The question is, how can we identify the types of disturbance and take account of them in interpretation? An understanding of decay processes, and of what we are unlikely to find in certain environments, is crucial for evaluating our sample of the material record. Geoarchaeology can be very helpful for assessing formation of natural and cultural strata, as can the study of artifact damage, fragmentation, and its *spatial analysis*. *Ethnoarchaeological* observations of historical and ongoing site formation processes provide invaluable clues about the range of

possibilities we should consider. These alterations do not diminish the value of the archaeological record but add to its richness and complexity.

Site Formation Processes

Alan P. Sullivan III[1] and William Flint Dibble[2]
[1]Department of Anthropology, University of Cincinnati, Cincinnati, OH, USA
[2]Department of Classics, University of Cincinnati, Cincinnati, OH, USA

Introduction

As core concepts in contemporary archaeology, site formation processes (SFP) are indispensable in building strong inferences about the cultural past (Schiffer 1987). SFP are implicated at every level of archaeological inquiry, from designing research to interpreting variation in artifact form, assemblage composition, feature content, space modification, and landscape evolution. Without question, understanding the origins and significance of variability is fundamental to determining the suitability of certain kinds of archaeological phenomena for particular research questions.

A *formation process* is any event or situation involving the interactions of humans, surfaces, matter, and the environment that affects the characteristics of the archaeological record (such as its spatial extent, depth, surface expression, or content diversity). Such events create anomalies in natural ecosystems (often referred to as "traces") that register these interactions and subsequent modifications to them. In fact, as a contemporary phenomenon, the archaeological record can be considered the *current* expression of the cumulative effects of formation processes (Sullivan 2008a).

Theoretically, the study of the archaeological record is enabled by a consideration of formation processes because archaeologists are interested in understanding which factors have contributed to archaeological variability. These and other concerns are covered by *formation theory*, an integrated corpus of concepts that focuses on understanding how the archaeological record expresses the properties that it does (Shott 2006). As well, formation theory inspires the development of relevant methods for identifying and incorporating an understanding of SFPs and their effects in inferring the histories of archaeological phenomena.

Definition

Typically, SFP are distinguished on the basis of the agents involved in producing traces. Anthropogenic formation processes (AFP, also called "cultural" formation processes) register modifications to surfaces and matter caused by human activity. In contrast, environmental formation processes (EFP, also called "natural" formation processes) modify anthropogenic surfaces and

arrangements of matter by the actions of earth dynamics, vegetation growth patterns, and animal behavior (Schiffer 1987).

Anthropogenic Formation Processes

AFP and their archaeological consequences can be discussed conveniently in terms of several classes. First, significant ethnoarchaeological and experimental research has concentrated on documenting the traces that arise on *specific types of artifacts* and how variation in their use-histories (from acquisition to discard) affects their form. The transformation (or flow) model of these processes has focused specifically on investigating how an object's attributes and performance characteristics are manipulated by humans, including variation introduced by discontinuities that arise among stages of artifact production, use, re-fashioning, and ultimately abandonment (Schiffer 2010). Archaeologically, provenance studies using strontium isotope ratios, for instance, have shown that the distances between the sources of ceramic materials (e.g., rock temper) and the locations of ceramic manufacture vary tremendously for different wares (Carter et al. 2011). With respect to organic artifacts, such as domesticated crops, isotopic studies have determined that the areas where such plants were grown differ dramatically and changed through time, from the contexts where they were processed and stored (Benson et al. 2009).

Second, equally consequential AFP studies have been conducted by ethnoarchaeologists and archaeologists on the formation histories of assemblages, that is, how variation arises and is registered by the accumulation, and ultimately the abandonment, of *different kinds of artifacts* on surfaces. Often referred to as "activity area" research, the investigation of these AFP is intended to provide a framework to infer the behavioral or organizational factors that are responsible for differences in the quantities, concentrations, and diversity of "floor-contact" artifacts (Enloe 2008). In addition, exploration of assemblage formation histories has promoted the development of "accumulations" research, which is designed to enable archaeologists to develop inferences about the amount of time it took for certain quantities of artifacts to build up in specific contexts (Varien and Mills 1997).

Third, the anthropogenic modification of space is a formation process that has a deep and broad history of investigation by architects, ethnographers, ethnoarchaeologists, and archaeologists (e.g., Nabokov and Easton 1989). In both ancient and modern contexts, studies of these AFP invariably entail consideration of the traces of construction activities – terrain modification, material acquisition, labor mobilization, and relative chronology – that are registered by surface anomalies (e.g., Burks and Cook 2011), stratigraphic relationships among surfaces (e.g., bonding and abutting relationships among walls), interfaces created by the installation of architectural features (e.g., postholes), and alterations to preexisting architectural forms (Harris 1979). In fact, the extent of earlier occupation, the degree of subsequent rebuilding, and even the sizes and shapes of razed structures can be inferred by mapping the traces of buried foundation trenches, the locations of displaced mud-brick fragments, or the remnants of bedrock modifications (Fig. 1).

Fourth, an increasing number of AFP studies, conducted by archaeologists and geoarchaeologists, has focused on determining the authenticity or integrity of "sites" and their contents. For example, in the case of Pompeii, despite the sudden eruption of Vesuvius and rapid burial of the city in CE 79, the integrity of the "snapshot" was greatly altered by post-eruptive anthropogenic activities, such as removal of valuable goods by the fleeing populace, later excavation and retrieval of objects by the Romans, and, much later, by the construction of a large drain in the seventeenth century (Allison 2004). Conversely, the presence of 17 wells completely filled with "typical" demolition debris, adjacent to and dating closely to the same period as the demolition of monumental structures, confirmed the authenticity of "Persian destruction" events that transpired in the Athenian Agora (c. 480/479 BCE [Shear 1993]).

Fifth, as archaeology itself has become institutionally mandated in regional planning studies, many archaeologists have turned their attention to landscape scales of analysis and,

Site Formation Processes, Fig. 1 Bedrock cuttings in the cliff face for multiple-story structures opposite the Chateau de Commarque (twelfth to eighteenth century CE; Photo by Jonida Martini)

Site Formation Processes, Fig. 2 The sixth-century CE basilica of San Nicola in Carcere, Rome. (Photo by Jonida Martini). The basilica was constructed over the foundations and incorporated the superstructure of three temples: the Temple of Spes (c. 250 BCE), the temple of Juno (second century BCE), and the Temple of Janus (CE 17)

understandably, to understanding the formation histories of regional archaeological records. Such studies have become particularly attractive as archaeologists have become more deeply involved in climate change studies (Kirch 2005). In addition, many of the millennia-old terrain modifications created by small- to mid-scale societies, such as now long-abandoned reservoirs and rock alignments, not only have resulted in permanent changes to drainages and ecosystems but provide, as well, sources of paleoenvironmental samples that register temporally sensitive rates of change in anthropogenic environments (e.g., McIntosh et al. 2000).

Finally, archaeologists worldwide have been documenting the historic and continuing extent of anthropogenic modifications to archaeological phenomena. For instance, it is not uncommon in prehistoric contexts for abandoned artifacts, such as sherds, to be reclaimed from their discard contexts and recycled as architectural elements; in these cases, the original design and performance characteristics of these ceramics have been "overprinted" and adapted for new purposes (Peña 2011). Similarly, in more recent contexts, ancient materials have been repurposed and given new meanings, as when Roman columns were incorporated in a medieval church (Fig. 2) and a

Site Formation Processes, Fig. 3 Prehistoric (CE 700–1200) metate (grinding stone) installed as a grave marker in the twentieth-century public cemetery at Grand Canyon National Park, Arizona

prehistoric metate was installed as a grave marker in a modern cemetery (Fig. 3).

Still, tragically, the vast majority of anthropogenic modifications to archaeological phenomena materialize as modern traces that significantly affect ancient ones. Some of these formation processes are intentional, but the effects are well understood and, hence, can be factored into archaeological interpretation, as in the case of "plow zone" assemblages (Hawkins 1998). Others, such as the effects of camping, hunting, and woodcutting on surface archaeological phenomena (Fig. 4), although inadvertent, are more difficult to incorporate in archaeological interpretation because their effects are just beginning to be studied systematically (Uphus et al. 2006). Of course, modern activities targeted specifically to relieve the archaeological record of "valuable" objects for the antiquities market are globally proscribed but represent, nonetheless, a major AFP that continues to affect the content and contextual integrity of archaeological records worldwide (Lazrus and Barker 2012).

Environmental Formation Processes

For each of the three broad classes of EFP – earth dynamics, vegetation growth patterns, and animal behavior – humans are uninvolved in the production of traces that affect the characteristics of the archaeological record (Schiffer 1987). These SFP add, alter, or obliterate traces involving matter, surfaces, and their relations that have accumulated in the archaeological record as a consequence of any of the aforementioned AFP. Often glossed by the term "turbations" (or disturbances), the study of these formation processes by geologists, geomorphologists, soil scientists, and archaeologists has accelerated significantly during the last two decades (e.g., Goldberg et al. 2001).

One category of earth EFP includes short-term, largely unpredictable events, such as earthquakes (Bottari et al. 2009), volcanic eruptions (Sheets 2006), and tsunamis (Cook and Abbott 2012), that can quickly and dramatically alter prevailing arrangements of matter, including architecture, as well as introduce matter to existing surfaces. Equally important, the fallout from these processes, over which humans have no control, can disrupt social systems, leading to widespread regional depopulation and profound ecosystem transformation (McIntosh et al. 2000). Although potentially devastating for local populations, these events often produce so-called "Pompeii" assemblages, which provide a "snapshot" of activities at the moment they were discontinued. In these cases, although preservation is often enhanced because of rapid burial, it is unclear how far back in time such arrangements of artifacts and contents of features can be projected; hence, Pompeii assemblages are often considered

Site Formation Processes, Fig. 4 Modern, illegal woodcutting has altered the surface archaeology of prehistoric fire-cracked-rock piles (*lower left-center* to *upper right-center*), Kaibab National Forest, Arizona

to be "end-biased," short-term, though comparatively rich, samples of ancient human activity (however, as noted above, even in the case of Pompeii itself, post-destruction AFP can greatly alter the integrity of the "snapshot" of ancient activity).

A second category of earth EFP includes long-term and highly predictable modifications to abandoned objects and surfaces that arise as consequences of erosion or sedimentation. The major archaeological consequence of slope wash and stream action is artifact displacement, which can result in either "false" concentrations of artifacts or dispersal and redeposition of artifacts from their original discard contexts (Dibble 2008). Alleged "hearths" at the famous Paleolithic site of Zhoukoudian in China, for instance, once thought to be the earliest evidence of hominin-controlled fire, have now been determined to be accumulations of fluvial sediments (Goldberg and Macphail 2006). Similarly, in arid environments, deflation (removal of fine-grained sediments by wind) can cause commingling (settling) of objects originally deposited on asynchronous surfaces, thereby increasing artifact density and assemblage diversity (Schiffer 1987). Also, experiments have shown that both fluvial and aeolian processes can affect artifact form by "rounding" or "dulling" artifact edges and surfaces (Skibo 2012). Other studies have demonstrated that chemical changes can occur on abandoned objects when, for example, their ground-contact surfaces become locations for the development of "desert varnish" (Goldberg and Macphail 2006).

Originally developed by paleobiologists to understand the mechanisms by which animals come to be represented in the fossil record, the effects of taphonomic processes are being explored by archaeologists to understand how burial and fossilization may skew the content of archaeological samples (Gifford 1978). For instance, certain kinds of remains, such as soft plants or animal hides, generally do not preserve well, if at all, unless they are carbonized, desiccated, mineralized, or waterlogged (Miksicek 1987). In some depositional situations, therefore, archaeologists now proceed cautiously knowing that the absence of fragile material classes can be considered evidence of absence (i.e., indicative of human selection) only after carefully assessing taphonomic factors (Ward and Larcombe 2003).

The second major class of EFP pertains to traces produced by the dynamics of vegetation growth patterns (e.g., establishment, expansion, and contraction of plant communities). Abandoned archaeological sites, particularly those

with architectural remains, provide highly productive microenvironments (composed of soft sediments that preferentially retain moisture) that encourage the development of abnormally dense vegetation, which has a number of consequences for the archaeological record. First, thick vegetation (such as impenetrable thickets in desert areas or jungles) may obscure the very remains that archaeologists are interested in locating either by pedestrian survey or by satellite remote sensing (Sullivan et al. 2012). Second, the presence of archaeological sites is often revealed by concentrations of "anomalous" species (e.g., deciduous trees in a conifer forest) that otherwise should not be present. Third, because of climate change, which can adversely influence ecosystem health (e.g., promote bark-beetle infestations), archaeological sites in conifer forests are highly susceptible to damage from wildfires, which can introduce charcoal to buried horizons, topple trees, and their rooting systems in abandoned structures (Fig. 5); encourage erosion of exposed (vegetation-free) surfaces; and accelerate artifact displacement by destabilizing the surfaces upon which the material reposes. Finally, a common problem worldwide is that of the "tree-throw" (or tree-fall), which has two expressions that can confound archaeological interpretation (Goldberg and Macphail 2006). The first type, rather benign, occurs when large trees are upended and their root balls become exposed to the elements (Fig. 6) Within a short period, rocks embraced by the root system become dislodged from the root ball and accumulate as small mounds that mimic anthropogenic rock piles (however, because humans select rocks, size-class analysis should distinguish anthropogenic mounds (Fig. 7) from tree-throw mounds).

The second type, which is significantly more problematic, occurs when trees established in

Site Formation Processes, Fig. 6 Exposed and eroding root ball of a windblown tree, Kaibab National Forest, Arizona. Note the wide variety of rock sizes in contrast to those of the fire-cracked-rock pile (Fig. 7 below)

Site Formation Processes, Fig. 5 Late nineteenth-century log cabin, probably affiliated with Navajo households, that has been affected by bark-beetle-infested pinyon trees, which have collapsed and become incorporated in the structure (Grand Canyon National Park, Arizona)

Site Formation Processes, Fig. 7 Large fire-cracked-rock pile that has been affected by tree growth. Note that the rock sizes are relatively uniform in comparison to those exposed in the root ball and mound of the windblown tree (Fig. 6 above), Kaibab National Forest, Arizona

Site Formation Processes, Fig. 8 Destruction caused by a windblown tree whose roots have penetrated a prehistoric structure

Site Formation Processes, Fig. 9 Ceramic and lithic artifacts brought to the surface of an archaeological site by a burrowing vertebrate

archaeological phenomena are uprooted, thereby bringing artifacts and other material from deeper levels to the surface (Fig. 8), creating pathways for the introduction of modern material to ancient surfaces, and exposing buried surfaces and perishable materials (which may increase the likelihood of their hastened destruction by exposure to natural forces such as freeze-thaw cycles or wet-dry cycles; Goldberg and Macphail 2006).

The last category of EFP, animal behavior, pertains to traces that are introduced to the archaeological record by virtue of the activities of burrowing (e.g., gophers, badgers) and non-burrowing vertebrates (e.g., deer, cattle, sheep, and carnivores). Burrowing animals tend to displace artifacts on surfaces, move ancient objects from subsurface to surface contexts (Fig. 9), introduce modern material to ancient surfaces (and vice versa), and create anomalous features in ancient deposits (tunnels or cavities of anomalously soft sediments referred to as "krotovina").

Large-sized non-burrowing animals, principally because of their numbers and "herding" characteristics, have the potential to affect surface-assemblage characteristics (artifact number and density) by trampling objects into ever-smaller pieces (Gifford 1978). Carnivores, such as coyotes, as well as most domesticated dogs and pigs, can consume significant amounts of zooarchaeological material. However, anatomical-element density and growth studies suggest that analyses of fragment frequencies can serve to identify such carnivore-ravaged assemblages (Fig. 10; Lyman 1994).

Historical Background

In many respects, consideration of SFP is as old as the discipline of archaeology itself (Lucas 2012). In both the Old and New Worlds, for example, explanations of the origins of some extraordinary archaeological phenomena (e.g., pyramids, crystal skulls, or "exotic" artifacts) entailed pre-scientific arguments of how the activities of extraterrestrial agents, trans-oceanic adventurers, or marginalized refugees from various population dispersion events were responsible for the formation of a fantastic, if not alien, archaeological record (Fagan 2005).

The centrality of SFP was elevated and became foregrounded in archaeological practice with the publication of Michael B. Schiffer's theoretical article entitled "Archaeological Context and Systemic Context" in 1972. This and subsequent publications (see Schiffer 2010) framed a discourse focused on understanding the properties, origins, and sources of variability of the archaeological record itself that created a vast literature, which continues to proliferate (Shott 2006). Nonetheless, the importance of SFP in archaeological research became forever institutionalized as a consequence of the attention they received in

Site Formation Processes, Fig. 10 Percentages of modern goat anatomical elements (MNI 64) that survived after being ravaged by domesticated dogs in a Hottentot village. (Data from Brain 1980). MD mandible, Hd distal humerus, Td distal tibia, Rp/Up proximal radius or proximal ulna, MTp proximal metatarsal, SC scapula, PE pelvis, MCp proximal metacarpal, MCd distal metacarpal, Rd distal radius, MTd distal metatarsal, Fp proximal femur, A Astragalus, C calcaneus, Tp proximal tibia, Fd distal femur, PH1–3 first through third phalanges, Hp proximal humerus

the context of three hotly contested controversies – the "Binford-Bordes" (1966–1970), "Pompeii Premise" (1981–1985), and "Grasshopper-Chavez Pass" (1984–1989) debates. These disputes pivoted around fundamental differences of opinion regarding SFP – do they produce an archaeological record that is a fossil imprint of human activity, a distortion of human behavior, or something else (Sullivan 2008a)?

With the benefit of several decades of research inspired by these and other controversies, archaeologists nowadays are far more inclined to approach variability by thinking in terms of determining the formation histories of archaeological phenomena rather than in terms of being constrained by the archaeological record's interpretive limitations that are inherently attributable to distortions, disturbances, fragmentary remains, or poor preservation (Bailey 2007). In fact, largely as a consequence of the introduction and wide adoption of geoscientific methods during the last 20 years, archaeologists now see what once were considered obstacles to interpretation as research opportunities to explain why artifacts have the properties they do (Weiner 2010) or to ascertain what accounts for differences in the sedimentary composition of occupation levels (Holliday 2004). Similarly, archaeologists have developed their own "internal" concepts and methods to hypothesize, for example, why some ancient settlements, when fully excavated, disclose many intact vessels whereas others have none at all (e.g., "abandonment-mode" analysis [Deal 2008]), and why some highly fragmented artifact assemblages can be reassembled rather thoroughly whereas others cannot (e.g., "refitting analysis" [Chapman and Gaydarska 2007]).

Key Issues/Current Debates

Now that the significance of SFP is firmly established in archaeological practice, it is clear that whatever knowledge and principles have been secured so far are barely sufficient to cover the vast majority of archaeological cases – familiar and unfamiliar – that are implicated by the investigation of increasingly sophisticated

archaeological questions. Hence, archaeologists worldwide are exploring two major lines of inquiry that focus directly on expanding the study of formation processes with respect to the following questions: How is knowledge of SFP acquired, and how is that knowledge best applied?

The first line of inquiry for acquiring knowledge of SFPs is broadly *anthropological* and has two interrelated strands. One strand engages the ethnographic record and seeks to establish, for instance, statistical regularities among subsistence economies, environmental variation, and technology that serve as the basis for models whose implications can be independently tested with archaeological cases (Enloe 2008). The second strand is ethnoarchaeological research, which creates new data and empirical generalizations regarding material relationships among architecture, social organization, craft specialization, settlement systems, and ideology (David and Kramer 2001). Together, these strands, once fully developed, would constitute a middle range theory in archaeology that enables archaeologists to refer interpretations of archaeological phenomena and their formation histories to a highly confirmed body of cross-cultural principles.

The second line of inquiry is *archaeological* and has two principal strands, as well. The first strand is experimental, often referred to as actualistic research, where a "known" situation is created in the field using artifacts or other objects, animal carcasses or bones, and experimental plots of plants, and modifications to the material and their locations are monitored over time, generally several months or years (e.g., Banning et al. 2011). The objective is to gain an appreciation for rates of decomposition, displacement, or changes in soil properties that can be used to interpret the effects of EFP on similar kinds of archaeological phenomena (e.g., Rösch et al. 2002). The second strand consists of investigations of archaeological phenomena that are intended to understand the effects of SFP that materialize over long periods of time (centuries or millennia) and, hence, cannot be studied experimentally. Examples of this line of inquiry include studies of artifact displacement involving measures of artifact orientation (Dibble 2008) and of the composition of "fill" deposits to ascertain whether "termination rituals," for example, were responsible for material that accumulated above the floors of abandoned ceremonial structures (Van Keuren and Roos 2013).

The issues raised by these two lines of inquiry involve considerations of hypothesis testing. For instance, application of SFP knowledge derived from the "anthropological" approach to archaeological phenomena largely entails analogical reasoning, which, depending on the relevance of the cases (and hence the strength of the analogy), can lead to Type I errors (falsely concluding that the same or similar cause of the variability documented in the "anthropological" case is responsible for the variability seen in the archaeological case). Essentially, this type of error prematurely closes consideration of alternative hypotheses for the origins of the archaeological phenomena being investigated, thereby narrowing our views of what the cultural past may have been like (which is a form of presentism or projection of current knowledge of the present into the past). In contrast, application of SFP knowledge developed by the "archaeological" approach relies far less on analogical arguments because it is based on either replicable (highly confirmed) experimental results or well-established geoscientific principles. In these cases, the likelihood of Type I errors is reduced, the biases related to presentism are largely eliminated, and the potential for discovering ethnographically unprecedented cultural pasts is amplified (Sullivan 2007).

A second issue in the study of formation processes involves the units of analysis by which AFP and EFP and their effects can be unambiguously identified. As sketched above, because early (1970s and 1980s) formation process studies sought to understand how the form and location of artifacts changed through time, it is not surprising that they focused on examining factors that contributed to coarse-grained differences in assemblage composition (inventories of complete vs. fragmentary ceramic vessels), provenience categories (fill vs. floor), or refuse categories (primary vs. secondary refuse). By the mid-1980s, it had become clear that the usefulness of these studies was constrained by the incorporation

of interpretation-laden units of analysis, that is, the terms of the categories themselves, such as debitage types (e.g., primary flake or biface-thinning flake), room types (e.g., habitation or storage), site types (e.g., limited-activity or habitation), or settlement-system types (e.g., logistical or residential) biased conclusions regarding the origins and subsequent histories of the archaeological phenomena being studied (Sullivan 2008a). With this realization, archaeologists began developing interpretation-neutral units of analysis and more relevant methods, such as micromorphology, size-class analysis, assemblage refitting, and contextual analysis, to understand objectively how variability arises as a consequence of the tandem operation of different AFP and EFP (Matthews et al. 1997).

Another related issue is the extent to which information regarding the performance characteristics of artifacts, largely derived from experimental and replication studies, can be applied to archaeological phenomena (Schiffer 2010). Studies of total assemblages have now revealed that, in many cases, the most common artifacts – on occupation surfaces, in features, and incorporated in architecture – are fragments whose performance characteristics at the time they came to be deposited in those contexts or repose on those surface are largely extraneous to those that were designed-in at the time of artifact manufacture (Peña 2011). The scope of such widespread "de-correlation" between designed-in performance characteristics of intact artifacts at the time-of-manufacture and their post-manufacture use-contexts is beginning to be appreciated by archaeologists worldwide as a significant AFP affecting assemblage variability and archaeological interpretation (Chapman and Gaydarska 2007).

An emerging issue is renewed interest in the temporal scales at which SFP operate. Advances in the precision of independent dating techniques have alerted archaeologists to the disjunction between when events may have transpired (dated events, which are technique-specific) and how long it took for the phenomena (e.g., ancient matter, surfaces, features) associated with those dated events to materialize (target events), which are of archaeological interest. These considerations fall broadly under "time perspectivism" (Bailey 2007) and oblige archaeologists to reset their thinking regarding palimpsests, abandonment mode, and the significance of equifinality in archaeological interpretation. With respect to palimpsests, which refer to aggregate accumulations of objects, at least four types have been delineated depending on whether the same depositional contexts and surfaces are involved: true, cumulative, spatial, and temporal. Clearly, one "site" may be constituted of any number of these types, depending on its formation history, before it is ultimately abandoned, which raises profound issues for the methods by which archaeologists can infer artifact, surface, and feature contemporaneity (Sullivan 2008b).

An equally important and, surprisingly, unresolved matter raised by these concerns is whether abandonment mode invariably trumps occupation mode (which would mean that the archaeological record indeed is a massive "true and cumulative" palimpsest). That is, do the palimpsests and arrangements of matter on surfaces and in strata at the time of abandonment so thoroughly obliterate or obscure previous AFP traces that reliable inferences about pre-abandonment behaviors are utterly unattainable? Current research suggests that palimpsests actually may work in favor of archaeological interpretation because they serve as different kinds of clocks that measure the formation of the archaeological record in different ways. For example, cumulative palimpsests, such as "middens" (variably dense concentrations of ceramic fragments, lithic artifacts, and other materials), register elapsed "time-averaged" formation histories of entire settlements (and their aggregate discard patterns), whereas spatial palimpsests register "end-biased" formation histories of individual surfaces. Although far from fully confirmed and widely applied, these theoretical SFP concepts are valuable because they provide an interpretive framework for appreciating, and ultimately controlling for, the equifinal origins of the archaeological record (Sullivan 2007).

International Perspectives

With the theoretical maturation of the discipline since the 1970s, variability is no longer seen as something that is "monumentalized," that is, forever limiting the development of archaeological inferences because of the inherent distortions, biases, or incompleteness of the archaeological record itself. To the contrary, consideration of SFP is a global practice in modern archaeology involving the study of a wide variety of phenomena ranging from surface scatters of lithic artifacts in Western Australia (Fanning et al. 2009), flood-control sewer systems in ancient Rome (Aldrete 2007), buried villages in Ohio (Burks and Cook 2011), and the pollen record of historic period land-use patterns in pre-planned industrialized towns in Massachusetts (Kelso 1993). Moreover, SFP studies have evolved from largely theoretical exercises, which were not uncommonly dismissed as "cautionary tales" with little explanatory value or methodological potential, to rigorously tested and widely applied investigations that focus on specific problems involving human behavior and their archaeological consequences, such as determining the extent of prehistoric ecosystem management by fire in North America (Roos et al. 2010), distinguishing differences in the origins and uses of small-scale thermal features in Africa (Mallol et al. 2007), and resolving the geochemical signatures of household waste management practices in the Philippines (Beck 2007).

Also, SFP are being used to test and revise historical accounts, thereby resetting the long-standing tradition that texts are privileged, indisputable sources of information about the cultural past. For example, in Greek archaeology, fine-fabric and decorated ceramic vessels have been referred to as *oinochoe* [literally, wine-pouring jugs] because texts and images indicated that they were intended to be used exclusively at wine-drinking parties. However, because both *oinochoe* and identically shaped but undecorated coarse-fabric "jugs" numerically dominate ceramics recovered from "period of use" layers at the bottom of ancient Greek wells, it is reasonable to conclude that both types were used to fetch water (Fig. 11). Similarly, a reanalysis of the construction phases and brick stamps in the Pantheon in Rome suggests that the bulk of its design and reconstruction was completed during the reign of Trajan (CE 98–117) and not that of Hadrian (CE 117–138), despite numerous ancient historical references in support of the latter interpretation (Hetland 2007).

Future Directions

After some initial indifference, incorporation of SFP in archaeological research is now standard practice worldwide. In fact, most archaeologists would agree that studying the origins, history, and interpretive significance of the archaeological record has the potential to reveal aspects of bygone behavior, social organization, subsistence economies, and land-use strategies that have not been observed or recorded by cultural anthropologists, ethnohistorians, or ancient historians. At the least, such inquiries encourage the development of hypotheses about evolutionary processes and anthropogenic landscape transformations that take generations to materialize and, hence, can be studied only with an archaeological record whose examination is informed by an understanding of how it formed and came to express the properties that it does (Lucas 2012). Hence, the role of SFP in future archaeological investigations is not only secure but will expand as archaeologists endeavor to reduce disciplinary ignorance regarding how information about the past is transmitted to and disclosed in the present (Sullivan 2007).

In fact, we predict that future SFP research will concentrate minimally on four problem areas. First, progress in understanding the AFP of common but poorly understood archaeological phenomena, such as artifact scatters, will occur with the adoption of interpretation-neutral units of analysis because experience has demonstrated that normative categories, such as limited-activity site or special-use site, obscure rather than reveal the origins of these deposits. Second, advances in the application of geoscience (Goldberg et al. 2001) will provide a basis for archaeologists to reassess interpretations of common archaeological phenomena whose formation was thought to

Site Formation Processes, Fig. 11 Counts of published vessels by type found in "period of use" layers from the bottom of Athenian wells (c. 600–200 BCE). Identically shaped coarse-tempered jugs and fine-tempered *oinochoe* ["wine-pouring" jugs], both equipped with a single handle and a spout, dominate such assemblages

be well understood, such as features (whose origins may be attributable more to EFP rather than AFP) and "fill" sequences of abandoned structures (whose origins may be attributable more to AFP than to EFP). Third, developments in appreciating the effects of long-ignored EFP that are widespread but not well understood at all, such as the deterioration and depositional consequences of multi-material structures and the extent of artifact commingling that arises because of pervasive inter-context (subsurface-surface-subsurface) artifact circulation, will emerge as interdisciplinary collaboration accelerates and becomes institutionalized (Killick 2008). Fourth, one persistent problem is understanding the extent to which, and the circumstances under which, variation in abandonment-mode overprints pre-abandonment (occupation) mode dynamics (i.e., determining the prevalence of "true" palimpsests). In contrast to the three preceding problem areas, solutions to this one may require inspiration from tightly controlled experimental studies in ethnoarchaeology and geoscience.

Professor Lord Colin Renfrew (1976: 2) boldly claimed that "every problem in archaeology starts as a problem in geoarchaeology."

S

Updating the scope of his proclamation with the benefit of more than three decades of sustained research on the topic, no archaeologist would be uncomfortable with the friendly amendment that *site formation processes* could be profitably substituted for "geoarchaeology." Looking forward, the study of SFP is poised to accelerate the identification of problematic and unwarranted assumptions about the meaning of archaeological variability that, in turn, will empower archaeologists worldwide to challenge orthodoxy, to unconstrain their interpretations, and to become consequential in revealing the nature and diversity of the cultural past.

Site Stewardship Programs

Sophia Kelly
School of Human Evolution and Social Change, Arizona State University, Tempe, AZ, USA

Introduction

Archaeological site stewardship programs are organizations of volunteers who assist with the protection, preservation, and interpretation of archaeological sites. The structure of site stewardship programs varies based on the type of archaeological resources protected, landownership, and the position of stewardship activities within volunteer programs (Kelly 2007). These programs operate on both public and private landholdings. In most programs, volunteers help to monitor archaeological sites by documenting any changes to the condition of particular sites at regular intervals. Volunteers in some programs also assist in collection management, laboratory work, site interpretation, and even the excavation of some sites (Davis 1990).

Through careful monitoring, stabilization, and public education, site stewardship programs can be a highly effective means of preventing both natural and human-caused damage to archaeological sites. Archaeological sites are affected by both environmental and human degradation. Environmental elements including erosion, wind, water, and sunlight can damage archaeological features and artifacts. Vandalism, looting, and unintentional damage inflicted on archaeological sites by humans can also destroy archaeological sites. Many programs report that site damage has decreased dramatically as a result of program initiatives (Kelly 2007).

Definition

Site stewardship programs represent a new movement towards public stewardship of archaeological resources (McManamon 1991; Thorne 1996: 2). State and federal protection strategies for archaeological resources originally limited public interaction with sensitive archaeological materials. In the mid- to late 1980s, however, federal and state governments adopted policies that relied on public education and active involvement in archaeological site protection. Most significantly, amendments to the Archaeological Resources Protection Act (ARPA) required federal land managers to ". . .establish a program to increase public awareness of the significance of the archaeological resources located on public lands and Indian lands and the need to protect such resources (1988 amendment to ARPA, Sec. 10c)." These new changes in attitude and legislation encouraged partnerships between federal and state agencies that resulted in the creation of the site stewardship programs in almost every region of the United States.

Most site stewardship programs function under a modest budget because nearly all labor is donated on a volunteer basis. Federal and state agencies support and manage some programs, while other programs operate as nonprofit organizations. Funds are typically used to hire a full- or part-time site stewardship coordinator and to pay for supplies related to monitoring or site stabilization activities. Funding sources for archaeological site stewardship programs vary depending on the resources protected and land ownership. Typical sources of monetary support include federal and state agencies, partnerships with local historical and archaeological societies and museums, and external grants.

The most important and sometimes only employee of site stewardship programs is the stewardship coordinator. The coordinator organizes volunteer labor, directs volunteer training and education, leads advertising and recruitment, and is each volunteer's main contact within the program. The coordinator's relationship with volunteers is the backbone of many programs. Regardless of the size of a stewardship program, consistent communication between coordinators and stewards is crucial to the efficient operation of the program and to the motivation of volunteers.

Attracting and maintaining good volunteers is essential to a successful volunteer stewardship program. Site stewardship programs must

carefully recruit volunteers who will not divulge sensitive site information. Site stewardship programs often require extensive training for their site stewards to ensure that volunteers will not intentionally or inadvertently cause harm to archaeological sites or artifacts. In most cases, training includes both a classroom and fieldwork component. Through training, programs emphasize the necessity to keep site locations secret. Often programs do not allow site stewards to bring visitors on their monitoring trips and require that volunteers sign confidentiality agreements. These measures help to ensure that only trained persons will visit archaeological sites.

Successful site stewardship programs recognize the reasons why people volunteer and address these motivations in volunteer activities. In many programs, stewards are invited to attend program meetings and presentations as well as regional conferences. Stewards can also participate in other fieldwork activities under professional supervision, such as special recording projects (e.g., documenting rock art panels), site damage assessments, land surveys, and site stabilization.

Regular communication between site stewardship coordinators and volunteers greatly enhances the volunteer experience as well as the efficiency of the program. Interaction with professional archaeologists and other people trained in cultural resource management is one of the most important things that volunteers seek and respond to in site stewardship programs. Coordinators should keep volunteers abreast of the progress towards program goals.

Volunteer recognition is a critical component of the recruitment and maintenance of site stewardship volunteers. Monitoring volunteers hours allows programs to recognize the contributions of individuals and to demonstrate that the program values the time that volunteers invest. Studies indicate that volunteer retention is higher in programs that monitor volunteer activities and reward volunteer service (Schwartz 1977; Field and Johnson 1993: 1629). In addition, many programs provide additional benefits to volunteers to demonstrate appreciation. For example, the Arizona Site Stewardship Program pays conference fees for volunteers to attend the Arizona Historic Preservation Conference. In programs such as the Nevada Site Stewardship program, volunteers have workman's compensation insurance as agency volunteers.

Many archaeological resources in the United States are related to the prehistoric and historic occupation of Native American tribes. The support and involvement of Native American groups in site stewardship initiatives is essential in areas where the majority of the archaeological sites are Native American. Site stewardship programs can help emphasize the connection between the protection and preservation of Native American archaeological resources and respect for native traditions. In addition, stewardship programs can facilitate interactions among Native American communities and archaeologists. For example, the Alutiiq Museum Site Stewardship Program in Alaska and the California Site Stewardship Program involve Native American communities as advisors, administrators, and stewards. These programs have also tailored program goals to fit those of local tribal governments. Finally, some tribal governments, such as the White Mountain Apache Tribe, have established site stewardship programs through their Tribal Historic Preservation Offices (Welch et al. 2009). These programs are directly run through the tribe for protection of archaeological resources within community boundaries.

Examples

The structure and operation of site stewardship programs depends on the landownership of archaeological sites and the resources that they serve to protect. Archaeological site stewardship programs can be a valuable component of protection plans for archaeological resources on both public and private lands. Programs that operate on public lands provide important assistance to land managers, who are often constrained by limited budgets and staff support. Site stewardship programs on private lands involve landowners in the protection of archaeological resources on private property.

Stewardship Programs on Federal and State Lands

Stewardship programs on public lands either are administered directly by agency land managers or function through nonprofit organizations that have allied with government land managers. Some of the largest site stewardship programs are part of volunteer programs established by major land management agencies. Volunteer programs that are associated with a federal agency and that involve a site stewardship component include the Forest Service's "Passport in Time" (PIT) program, the National Park Service's "Volunteers in Parks" (VIP) program, and the Tennessee Valley Authority's "A Thousand Eyes" program. Some federal agencies have also established independent site stewardship programs, such as the BLM's "Adventures in the Past" and the Forest Service's "Partners in Preservation" programs. State-sponsored site stewardship programs include the Georgia Underwater Archaeology Program, which involves both professional archaeologists and avocational scuba divers in the protection of Georgia's submerged archaeological resources (Burns and Crass 2006). Site stewardship programs can also operate through partnerships among several federal and state agencies. The New Mexico Site Watch program is one notable example of a collaboration among state and federal agencies. This program was established by the New Mexico State Historic Preservation Office in partnership with the National Park Service, the Bureau of Land Management, and the Forest Service to monitor archaeological resources in various locations in New Mexico. Finally, many site stewardship programs that monitor archaeological sites on public lands are nonprofit organizations that collaborate with federal and state agencies. Examples include the San Juan Mountains Site Stewardship Program in Colorado and the stewardship program run through the New York State Submerged Heritage Preserves.

Site stewardship programs serve as "watchdogs" for archaeological sites. These programs can provide support to federal and state land managers in several critical ways. They can assist land managers by establishing long-term protection strategies for sites. With consistent monitoring, the effects of environmental and human degradation on archaeological sites can be controlled. Site stewardship programs that are external to public agencies can also serve as advocates for the protection of archaeological resources on state and federal lands. Land managers, who are often charged with a myriad of tasks, may not be aware of dangers posed to archaeological sites on particular parcels of land. Volunteers in these programs can provide local knowledge of these threats and can serve as liaisons between land managers and the community. Site stewardship programs can help emphasize the importance of archaeological resource protection while providing support for these safeguards. Many programs have noted that the intentional damage of sites, either through vandalism or looting, significantly decreased after the implementation of their programs (Kelly 2007). The knowledge that site stewards regularly patrol an area is often enough to deter would-be vandals and looters.

As liaisons, site stewardship programs facilitate interaction and collaboration among government agencies, resource managers, archaeologists, and the public. Agency employees may be viewed as outsiders, while site stewards can offer a local perspective on resource management within communities. Site stewardship programs also provide a conduit through which local law enforcement and archaeologists can reach out to the public about the protection of archaeological resources in a positive manner. In general, people do not respond to negative messages that emphasize sanctions against looting and vandalism (Hoffman 1991; Simon 1994).

The Arizona Site Stewardship Program is an example of a program that uses positive public messages to address site destruction. In particular, the program educates the public on the importance of preserving archaeological sites and artifacts in Arizona. The program also highlights the variety of archaeological sites and museums that offer tours and provide additional information about the historic and ancient past of Arizona. Through these initiatives, the Arizona Site Stewardship Program educates the public on the importance of preserving archaeological resources and provides them with a

safe and fun way to learn more about local archaeology. Information and access to sites not only provides the public with a positive way to experience archaeology but deters would-be vandals and looters (Hoffman 1991).

Stewardship on Private Lands

Although the majority of site stewardship programs operate on public lands and waterways, some programs protect archaeological sites on private lands. These programs are generally run through the State Historic Preservation Office or through partnerships with other state and local agencies. Some programs use volunteer site stewards to monitor archaeological sites on private lands through agreements with the landowners. In other programs, landowners themselves agree to become stewards of archaeological sites on their land. Stewardship programs on private lands involve the cooperation of landowners who act as stewards of cultural materials on their own property. In most cases, private landowners sign an agreement with the local State Historic Preservation Office (SHPO) to protect archaeological materials.

Site stewardship programs on private lands play an important role in safeguarding sites and involving the public in cultural resource protection (Henderson 1989), because only a tiny fraction of the USA is under government protection. They demonstrate that archaeological sites can be effectively monitored through a relatively small monetary investment and that site conservation does not always require land purchases. These programs will be increasingly important in the coming years as more land is developed and sites are put at greater risk. For instance, the Archaeological Conservancy, which protects archaeological sites on private lands, now includes parcels from across the country.

Studies have shown that site stewardship programs that actively involve landowners in the protection of archaeological resources on their lands are much more successful than those that do not. These programs rely on incentives from local and state governments to join the stewardship program. Sanctions and restrictions against landowners, nicknamed "big stick" methods of site protection, are often met with hostility and prove ineffective in the long run (Simon 1994).

Underwater Archaeological Site Stewardship Programs

Site stewardship programs devoted to the monitoring and protection of underwater archaeological resources play a vital role in comprehensive site protection (Elliott et al. 2000). Many underwater site stewardship programs were developed in response to the Abandoned Shipwreck Act of 1987 and its advisory guidelines. These guidelines encourage the development of shipwreck preserves and the cooperation of both government agencies and the public in the management and protection of shipwreck sites. Recreational and heritage tourism stimulated by shipwreck preserves provide much needed attention to underwater stewardship programs. In the case of the Rhode Island Marine Archaeology Program (RIMAP), the discovery of the HMS Endeavor was the catalyst for public concern over the protection of underwater archaeological sites in the region. For the stewardship program associated with the New York State Submerged Heritage Preserves, the discovery of the land tortoise initiated the development of a shipwreck preserve system. The Texas Historical Commission established its Marine Stewards Group as a result of diver public interest generated by the State's recovery of French explorer Robert Cavelier Sieur de La Salle's ship La Belle from the waters of Matagorda Bay.

Summary

Archaeological site stewardship programs have become an integral part of archaeological site protection in the United States. These programs use public education and the active involvement of nonprofessional archaeologists to prevent or reduce environmental and human impacts on sensitive cultural resources. The structure of site stewardship programs varies considerably and includes archaeological protection on both public private lands, of both terrestrial and underwater archaeological resources. Stewardship programs originate from new attitudes about site protection that recognize the importance of public education and involvement in safeguarding archaeological resources.

Site Visitation and Interpretation: Management

Melanie J. Kingsley[1] and Douglas C. Comer[2]
[1]Department of Anthropology, Brandeis University, Waltham, MA, USA
[2]ICOMOS International Scientific Committee on Archaeological Heritage Management (ICAHM), Cultural Site Research and Management, Inc. (CSRM), Baltimore, MD, USA

Introduction

Typical archaeological and historical sites contain a multitude of resources about which they seek to preserve and inform the public. Archaeological resources, cultural landscapes, monuments, tombs, ethnographic resources, historic and

prehistoric structures, and museum collections are some of the major categories that must be juggled and integrated into visitation and cultural resources management plans. Archaeological materials are nonrenewable and irreplaceable; these considerations should guide the management of archaeological sites.

Definition

Within the context of site visitation, *interpretation* of heritage serves to communicate information about the origin and purpose of natural or cultural resources. Interpretation provides the means by which to better appreciate and understand archaeological sites through experience and interaction. Interpretation is not simply presentation for that implies a planned arrangement of information providing a one-way form of communication from scholars, heritage professionals, and the like (Silberman 2006). Rather, interpretation goes beyond to consider the totality of activities, research, and general creativity generated by an interaction with a cultural site. The first goal of interpretation at archaeological sites should be the preservation of archaeological materials at the site, and no interpretive activities that endanger archaeological materials should be permitted. Interpretation at archaeological sites must make visitors aware of site vulnerabilities and should build a constituency for the sustainable management of the site.

Key Issues/Current Debates/Future Directions/Examples

Interpretation

The presentation of archaeological, historical, and present-day heritage sites is incomplete without interpretation. Interpretation, as the term is used here, is provided for a public audience; it is a form of outreach that informs and, ideally, provokes contained interest and conversation. It is a means by which to better appreciate and understand the experience of visiting an archaeological site. Properly done, it is a guide to extracting meaning from the site, which provides the information needed to navigate the site in ways chosen by the visitor. Most importantly, it is a fundamental element in establishing and maintaining site sustainability.

The presentation of interpretation of historical context to a public also serves to highlight what is deemed significant and, through this act, can give strength to communities and provide a sense of place and belonging. Who creates such interpretation, however, raises question of ownership of heritage, social inclusion and exclusion, and the very politics of identity making. Interpretation gives voice to certain views of the past, and, in feasible and deft ways, these voices should be identified by reference to the scholarship and oral or written histories that have been used in preparing interpretive materials.

Site managers, archaeologists, and others seek to address three major questions in any interpretive plan: (1) How, when, why, and by whom was the site and surrounding landscape used in ancient times? (2) Why was the site a center of activity (in whatever manner that is defined)? (3) Why was the site important then, and why is the site important now? In order to disseminate such information, a master narrative is often created which serves as the basis for interpretation of all specific points of interest within the site. These narratives are then used as adaptable texts from which exhibits, brochures, training modules, and other interpretive devices are generated. However, all interpretive plans should accept that visitors have their own individual points of view and therefore should encourage dialogue.

Effective interpretive frameworks link specific tangible artifacts, buildings, and places with ideas, events, and concepts. Importantly, this interpretation should relate to wider social, cultural, historical, and natural contexts and settings (ICOMOS Ename 2007).

Role of Tourists

Clifford (1997) defines tourism as a contact zone, a place where identities are made and transculturation occurs. Archaeological and historical sites, therefore, become not only media through which cultures and events are presented but also

where the experience of being a tourist changes one's sense of self. As a result, there are a multitude of protagonists who affect, shape, and delineate the tourist's experience. These actors include scholars and scientists, national governments and agencies, local governments, local indigenous groups, nongovernmental organizations (NGOs), property owners, and the visitors themselves. Tourists can be agents of destruction or support to an archaeological site; the interpretive program should be designed to encourage the latter role.

The Stakeholders

The creation of an interpretive plan should be a community activity so as to include the multitude of their voices and, simultaneously, be informed by archaeological data. As Byrne (1991) and Smith (2000) have noted, the operation of conservation in the heritage management industry has often promoted and maintained dominant colonial positions. The very linearity of how sites discuss past events gives precedence to Western scientific explanation. As a result, the management of sites and the creation of interpretive plans create tension between national and local government agencies, indigenous groups, and property owners (Meskell 2001).

The ICOMOS Charter for the Interpretation and Presentation of Cultural Heritage Site (previously called the Ename Charter) is cognizant of these difficulties. This ICOMOS Charter was finalized in 2007 to highlight that role of interpretation and preservation. The Charter lays out the importance of taking into account the cultural contributions of all communities associated with a site, including minority groups as well as the interests of associated communities, property owners, governmental authorities, site managers, scholars, tourism operators, private investors, employees, and volunteers, and including them in the development of interpretive programs. The recent Statement of Menorca (2012), formulated by the International Council on Archaeological Heritage Management, expresses concern that archaeological sites, especially in developing countries, are increasingly seen as economic engines as opposed to being repositories of scientific and historic information or as places that enhance appreciation and understanding of human creativity and accomplishments. To correct this imbalance, it calls for the formulation of standards for the management and protection of archaeological sites, which should include the use of interpretation as a component of effective management. These standards should accommodate non-Western perceptions and thoughts about the meanings of material culture.

Recent scholarship by indigenous scholars and activists (e.g., Condori Mamami 1989; Cojti Ren 2006) demonstrates the, at times, systematic delinking of present indigenous groups to their past. As cultural heritage sites often remain important to current indigenous groups, traditionally associated groups to a site, therefore, should increasingly be permitted to pursue customary religious, subsistence, and other cultural practices at a site. Such continuing access to and use of traditional resources are often essential to the survival of family, community, or regional cultural systems, including patterns of belief, economic, and religious life. Due to the importance of such activities, however, site managers should not direct visitor attention to the performance of religious observances in particular unless these traditionally affiliated with the site lands or resources so desired.

Tourism Versus Protection

The difficulty faced by site managers is to balance tourism against the future protection of the site. Starting as early as the 1970s, researchers began looking at the impact of visitors on national parks and other protected areas (Flood 1982; Jacobs and Gale 1994; Forrest 1995). This research was amplified by investigations into artifact displacement as a result of agricultural practices or natural erosion (Cameron et al. 1990; Schofield 1991). It was not until recently, however, that some researchers turned their attention not just to the unintentional impact of specific categories of visitors on structural longevity but also to more active disturbances, movement, or outright removal of stone or other loose artifacts from sites by tourists. In their study, Migley et al. (1998) discovered that disturbance levels of artifacts did not decline evenly with an increasing

distance from the central visitor area; as a result, the impact of tourism goes beyond the most traveled paths.

Comer (2011) argues that the most common and often the greatest threat to site preservation is from development associated with providing amenities to tourists. Such developments often change regional hydrology. At Petra, for example, construction of hotels, restaurants, parking lots, roads, and other impervious surfaces produces flooding that damages ancient structures by exposing them to chemical-laden floodwater, which washes away subsurface archaeological deposits. Other sorts of hydrological change produced by tourism can also be catastrophic. At Angkor, water pumped from the ground for use by tourists at hotels and restaurants is threatening soil stability and thus the foundations of the ancient monuments. Other threats arise from social discord promoted by competition among groups for economic gain associated with tourism. Such discord can ultimately promote political instability if multinational corporations eliminate economic opportunities for local populations. Discord and political instability greatly reduce the capacity to effectively manage archaeological sites.

Signage, Walkways, and the Site Experience

Balancing the protection and long-term management of a site with daily tourists requires, among other things, well-delineated signage and walkways. It is important for walkways to be cleanly cut and maintained but also organized in such a way as to move visitors in and out of major throughways without producing erosion or encouraging tourists to sit on or rest against ancient structures. For this reason, benches or other seating, if possible in a shaded location, should be provided. Paths should never take tourists to remote, unobserved locations at archaeological sites where looting, vandalism (often in the form of graffiti, attempts to obtain rubbings, or even removal of architectural details), vending of looted antiquities, or use of ancient structures as ad hoc toilet facilities will eventually occur. The signage at any site should provide concise, well-worded text and associated images that provide a basic understanding of the meaning and significance of the monuments; limited text is fundamental to maintaining the movement of visitors while at the same time providing the educative material necessary for a pleasant and well-rounded visit.

In all, a comprehensive signage program includes way finding signs to help visitors identify the proper course, interpretive signs (wayside exhibits), orientation signs, trailhead information, consistent safety and warning information, and a Plan Your Visit sign at the entrance.

The site experience, however, begins before a visitor even arrives at the site in question. General information about the history of the site and how to visit it are often disseminated through a multitude of media, such as the Internet, or key hotels that educate individuals about coming to see the specific cultural heritage. This orientation includes maps, what to expect during the course of a visit, information about the services available to visitors, and a site bulletin highlighting points of interest of the specific tours or trails available. The Internet and individual site websites have become fundamental in this task; importantly, such websites manage visitor expectations by providing an introduction to interpretive themes, points of interest inside the park, and rules of behavior.

Site Management

The essence of site management is structuring visitor flow into a site so as not to exceed its carrying capacity. Carrying capacity can be concisely defined as the type and level of visitor use that can be accommodated while sustaining desired resource and social conditions. Visitation exceeds carrying capacity when it damages cultural or natural resources, renders the quality of the visitor experience less than that desired by either the visitor or management, or degrades the quality of life for the inhabitants of local communities.

Interpretation at an archaeological site is a tool of site management. Preservation of archaeological materials is paramount; other interpretive objectives, including generating income and providing an experience that

produce shared memories which are important to the development of group identities, must be served in ways that do not damage archaeological materials. For that reason, most interpretive programs and activities should take place outside of the archaeological site, preferably in local communities that can then realize economic benefit from hosting such activities. The experience of visiting the site is as a rule best interpreted elsewhere.

The site experience should be unique to place, or at least exemplary of a type of place. Therefore, it is necessary to eliminate sensory experience incompatible with the experience of that location. This includes viewshed, sounds, smells, and light pollution. It also includes eliminating the press of crowds in locations that were in ancient times places of contemplation or at places that are conducive to contemplation today.

Commercial Uses

Outside of the typical tourist visit and the economic benefits they can bring, archaeological and historical sites also become centers of political, social, or artistic interest that bring potentially high-impact activities to the site. These could include photography, filming programs, aircraft overflights, and recreational vehicles.

Film and photography of a site are important aspects of promoting protection, information, and general public enjoyment of cultural heritage resources. Managers of these resources may actively assist in filming and photography activities that serve this purpose and would not adversely affect the site. Entertainment interest in cultural heritage sites, however, usually exceeds these parameters. In such cases, a permit should be required for any filming or photography that (1) involves the use of a model, set, or prop; (2) requires entry into a closed area; (3) requires access to the site after normal working hours; (4) requires heavy equipment and its transport around a site. Securing a large performance bond is essential; despite stated intentions, no matter how sincere, it is common that archaeological and historical sites require substantial cleaning and even repair following filming. Film company budgets are often more depleted than anticipated by the film company after work on location.

Aviation is a necessary and acceptable management tool, but its uses go beyond site management and administrative purposes to include military, commercial, and general aviation. Noise and vibrations from touristic overflights can adversely affect a site's resources and values and interfere with visitor enjoyment. As such, these should be mitigated as much as possible.

Similarly, off-road vehicle use should be carefully planned and regulated due to their high impact on a landscape. Roads and areas may be designated for such vehicles only in locales in where studies indicate that there will be no adverse impacts on an area's natural, cultural, scenic, and esthetic values, and in consideration of other visitor uses. Such use should be carefully monitored and regulated. The use of off-highway vehicles by site managers should be limited to what is necessary to manage the public use of designated off-road vehicle routes and areas; to conduct emergency operations; and to accomplish essential maintenance, construction, and resource protection activities that cannot be accomplished reasonably by other means.

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea

Yuri E. Demidenko
Crimean Branch, Institute of Archaeology, National Ukrainian Academy of Sciences, Simferopol, Crimea, Ukraine

Introduction

From the 1920s until the 1990s, the Siuren I rockshelter was the only Crimean Paleolithic site with an archaeological sequence that was thought to represent almost the entire Crimean Upper Paleolithic industrial and chronological succession, additionally with an Early Upper Paleolithic component at its base. Siuren I was and is still considered to be a key site for the Crimean Upper Paleolithic. Some archaeologists have also interpreted many of the site's lithic assemblages as Aurignacian, making Siuren I a significant site among the few true Aurignacian sites in Eastern Europe. New excavations at Siuren I in the 1990s yielded both new data regarding the site's archaeological context and absolute dates.

The site (44° 58′ N; 34° 08′ E) is situated near the high road from Bakhchisarai to Yalta, 0.5 km from Tankovoe village (formerly Biuk-Siuren) and 13 km south of the town of Bakhchisarai, in southwestern Crimea. It is one of two rockshelters (Siuren II is a Final Paleolithic site) located on the right bank of the Belbek River at its narrowest point ("Belbek Gate") where it cuts through the cliffs of the second range of the Crimean Mountains. Siuren I is a large south-facing rockshelter, 43 m wide, 15 m deep, and 9–10 m thick with an elevation of 15–17 m above the present-day level of the Belbek River.

Key Issues/Current Debates/Future Directions/Examples

History of Investigations at Siuren I and Its Archaeological Interpretations

The archaeological site at the Siuren I rockshelter was discovered and first excavated in 1879–1880 by the pioneer of Crimean prehistoric archaeology, K.S. Merejkowski (St. Petersburg). The excavations were carried out in the central part of the rockshelter near its back wall over an area of about 60 sq. m (Fig. 1). At the time, two Paleolithic layers were identified, although due to poor publications, Siuren I was considered as a doubtful site for more than 40 years (Bonch-Osmolowski 1934).

It was only after the 1926–1929 excavations by the then famous Soviet Paleolithic archaeologist Gleb A. Bonch-Osmolowski that the site was finally recognized as a key site for Crimean Upper Paleolithic. Up to 120 sq. m were excavated and three cultural layers identified within the deposits. These layers were separated by huge limestone blocks, resulting from different rockfall events from the shelter roof (Fig. 2). Although Bonch-Osmolowski distinguished several artificial horizons and even some hearth/ashy lenses within each layer during the excavations, he later combined the finds from each layer into three assemblages on the basis of the rather homogeneous industrial characteristics of the artifacts and his belief that deposition occurred rapidly. The three cultural layers defined by Bonch-Osmolowski (1934) represented, in his view, three stages of Aurignacian development: (1) lower layer (over 85 sq. m excavated) – "Lower Aurignacian" with some Mousterian-type artifacts, core-like end scrapers and numerous microliths with fine retouch; (2) middle layer (over 95 sq. m excavated) – "Middle Aurignacian" with carinated end scrapers and busked burins; and (3) upper layer (over 120 sq. m excavated) – "Upper Aurignacian" with Gravette points and numerous backed bladelets. Accordingly, he placed the Siuren I Upper Paleolithic into European context, finding similar complexes in Europe.

Such Aurignacian interpretations of the Siuren I assemblages were not, however, supported in Soviet archaeology. Instead, it was proposed that the rockshelter's layers showed the entire developmental sequence of the Crimean Upper

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea, Fig. 1 Siuren I. Map of the excavations. (Modified after Vekilova 1957: Fig. 2 on p. 237). *1*: the rockshelter's back wall; *2*: drip line; *3*: Merejkowski's excavation area (1879–1880); *4*: Bonch-Osmolowski's excavation areas (1926–1929); *5*: Tarasov's excavation area (1981–1982); *6*: new excavation areas (1995–1997); *7*: main stratigraphic profiles

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea, Fig. 2 Siuren I. Stratigraphic profile of Bonch-Osmolowski's 1926–1927 longitudinal trench (*squares* 12 A-M), eastern side. (After Vekilova 1957: Fig. 4 on p. 240). *1*: the rockshelter's back wall; *2*: numbers of lithological strata (*2*: upper cultural layer, *3*: middle cultural layer, *4*: lower cultural layer); *3*: huge limestone blocks and slabs representing different rock fall phases from the roof of the rockshelter; *4*: direction of huge limestone blocks and slabs falls; *5*: hearth/ashy lenses; *6*: mammoth bone finds in archaeologically sterile lithological layer 5 (lower part)

Paleolithic with such "epochal dates": "*Aurignacian*" for the lower layer, "*time of Solutrean and possibly the beginning of Magdalenian*" for the middle layer, and "*time of Late Magdalenian and Early Azilian*" for the upper layer (Vekilova 1957). Siuren I and Crimea as a whole were also placed within the "*Mediterranean-African*" Upper Paleolithic zone although the Siuren I assemblages also have analogies in the southern Caucasus (Georgia) to the east. Vekilova's "chronological" interpretations for the Siuren archaeological context, demonstrating the whole Crimean Upper Paleolithic sequence, were widely accepted in Soviet archaeology. The Aurignacian attribution of the assemblages from the rockshelter's lower and middle layers was also lost, which is why they were later assigned to the unclear "*Aurignacoid route of Upper Paleolithic development in Eastern Europe*" and dated to the Last Glacial Maximum (c. 20–18,000 BP) (Anikovich 1992). On the other hand, Bonch-Osmolowski's Aurignacian definitions for the lower and middle layer assemblages were supported and developed by European archaeologists (since Peyrony 1948). Thus, there were two opposed interpretations of the lower and middle layer assemblages until the collapse of the USSR in the 1990s: mostly non-Aurignacian and simply an Early Upper Paleolithic attribution in Soviet archaeology and definite Aurignacian attribution in European archaeology.

To resolve the non-Aurignacian/Aurignacian question for Siuren I, new excavations were undertaken at the site in 1994–1997 by a joint Ukrainian-Belgian team headed by V.P. Chabai and M. Otte. These took place in an area of 12 sq. m in the western part of the rockshelter (Fig. 1). Correlation between new stratigraphic units and Bonch-Osmolowski's layers could be made: the lower layer corresponds to Unit G,

middle layer to Unit F, and upper layer to Units A–E. Additionally, a new unit (H) was discovered below Unit G.

Based on results from modern excavations, reanalysis of the 1920s assemblages, and evaluation of the information available for the original 1879–1880 excavation, the archaeological sequence of the site now includes seven different periods of human occupation from c. 31–30 to c. 12–11 ky BP (all dates discussed here are uncalibrated) within c. 6 m of deposits (Fig. 3). This stratigraphic sequence is represented by alternating limestone *éboulis* layers and sandy, silty-clay/clayey layers, where the rock layers account for more of the sequence than sedimentary layers (Demidenko et al. 1998, 2012; Demidenko 2000; Demidenko and Otte 2000–2001).

Assemblages from the 1920s lower layer/1990s Unit G (with stratigraphically distinct sublevels Gd, Gc1-Gc2, Gb1-Gb2, Ga) and lowermost Unit H represent two alternative occupations periods at the rockshelter no later than the Arcy Interstadial (c. 31–30,000 BP). The first is attributed to the Middle Paleolithic (MP) Crimean Micoquian Tradition (Kiik-Koba type industry) produced by Neanderthals (Fig. 4), and the second to the European Proto-Aurignacian with Dufour bladelets produced by modern *Homo sapiens* (Fig. 5).

The 1920s middle layer/1990s Unit F (with stratigraphically distinct sublevels Fc, Fb1-Fb2, Fa3, Fa1-Fa2) contains assemblages attributed to the Late/Evolved Aurignacian with Roc de Combe bladelets during either the Arcy Interstadial (c. 31–30,000 BP) or the Maisières Interstadial (c. 29,000–28,000 BP) (Fig. 6a: 1–26).

In the 1920s upper layer and Units A–E, it is possible to identify four human occupation phases:

- Late/Evolved Aurignacian (c. 27,000 BP?): Unit E and part of the lowermost finds in the upper layer (Fig. 6b: 1–2)
- Late Gravettian (c. 24/23,000–20,000 BP?): Unit D and some finds in the 3rd "excavation horizon" of the upper layer (Fig. 7)
- Epi-Gravettian (c. 19–18,000 to 15,000 BP?): Unit A (not in situ), a few redeposited tools in humic deposits and most finds in the 1st and 2nd "excavation horizons" of the upper layer (Fig. 8a: 1–11)
- Final Paleolithic "Crimean Azilian" (Shan-Koba industry) (Allerød Interstadial – c. 12, 11,000 BP): western and eastern discrete "find spots"(c. 8 sq. m each) in the 1st and 2nd "excavation horizons" of the upper layer (Fig. 8b: 1–10)

The proposed chronology for each occupation phase is based on three AMS dates on ungulate bones from Units H, G, and F (Unit H: 28,200 ± 440 BP (OxA-8249); level Ga, the uppermost level of Unit G: 28,450 ± 600 BP (OxA-5154); sublevel Fb2: 29,950 ± 700 BP (OxA-5155)), faunal data indicating a rather temperate climate during sediment deposition of Units H, G, and F (López Bayón 1998; Pettitt 1998) and industrial comparisons of the Siuren assemblages with techno-typologically similar and well-dated industries in Crimea and Europe. It should be also emphasized here that five other ungulate bone samples from Unit F (level Fb1-Fb2), Unit G (one sample from level Gb1-Gb2 and two samples from level Gc1-Gc2), and Unit H (one sample) were not dated by the Oxford radiocarbon laboratory because of collagen problems (Demidenko et al. 2012). At the same time, three dating attempts on charcoal samples by the Louvain-la-Neuve (Belgium) and Oxford laboratories were either too young to be Upper Paleolithic or had collagen problems, which is why subsequent dating attempts concentrated on ungulate bone.

Interpretations of the chronology of the Siuren I industries have the following implications for the lower (Units H–G) and middle (Unit F) deposits. The co-occurrence of Micoquian and Proto-Aurignacian artifacts in Units H and G testifies to the geochronological coexistence of MP Neandertals and EUP *Homo sapiens* in Crimea c. 30,000 BP. A chronological gap between the Micoquian and Proto-Aurignacian assemblages (Units H and G) and the Late/Evolved Aurignacian (Unit F) is either nearly absent or quite short, making it possible for modern *Homo*

S

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea, Fig. 4 Siuren I. Units H and G (1990s), Middle Paleolithic Crimean Micoquian Tradition (Kiik-Koba type industry) flint artifacts *1–7*: unifacial and bifacial convergent tools; *8–12*: retouch and rejuvenation flakes and chips from unifacial and bifacial tools secondary treatment processes

sapiens with a Late/Evolved Aurignacian industry to quickly replace the previous inhabitants of Siuren I. As a result, this site not only occupies an important place within the MP-UP transitional period in Crimea but also serves to support both very late survival of Micoquian Neanderthals and the very late appearance of modern *Homo sapiens* and the Proto-Aurignacian here (Chabai 2000, 2003, 2004; Demidenko 2008). However, such a late Proto-Aurignacian Arcy Interstadial geochronology with AMS dates around 28,000 BP was not accepted by most European colleagues. In Western Europe, the Proto-Aurignacian is usually older, radiocarbon dated from c. 37–36,000 to 34–33,000 BP. The proposed Siuren I Proto-Aurignacian chronology could be too young, although the period of c. 30–28,000 BP is still within the broader Aurignacian time span. Therefore, it cannot be excluded that European Proto-Aurignacian *Homo sapiens* indeed penetrated into the south of Eastern Europe after occupation of southern and middle territories in Western and Central Europe. The Siuren I Proto-Aurignacian geochronological issue has also led to major debates on the Siuren I Late/Evolved Aurignacian and its significance for European Late/Evolved Aurignacian research. The Unit F assemblage not only perfectly fits the Western European Late/Evolved Aurignacian definition by having the

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea, Fig. 5 Siuren I. Units H and G (1990s), Proto-Aurignacian flint artifacts and a shell bead *1–11*: alternatively retouched Dufour bladelets and microblades of Dufour subtype; *12–16*: dorsally and alternatively retouched Font-Yves and Krems points; *17–19*: bladelet "carinated" cores; *20–21*: thick-shouldered end scrapers; *22*: *Apporhais pes pelicani* shell bead

"whole carinated piece package" (bladelet "carinated" cores and both carinated end scrapers and burins) and a single AMS date around 29,000 BP but also has the largest series of Dufour and pseudo-Dufour microblades of Roc de Combe subtype (68 specimens) in all of Europe.

Despite advances with the AMS dates obtained after the 1990s excavations, further dates were needed to provide additional support, leading to the very recent dating program for Siuren I.

Siuren I Dating Results in 2009–2011

From 2009 to 2011, a team of researchers (Yu.E. Demidenko, M. Otte, and P. Noiret (University of Liège) and Ph. Nigst and S. Talamo (Max Planck Institute for Evolutionary Anthropology, Leipzig, Germany)) joined to systematically date ungulate bones from Units H, G, and F (Demidenko et al. 2012; Demidenko in press). In total, 25 samples were sent to the Oxford, Groningen, and Beta Analytic laboratories. The attempts were carried out on two groups of bone samples. One was composed of samples from eight bone tools: two Micoquian bone retouchers from Unit G, two Proto-Aurignacian points and an awl from Unit G, and two Late/Evolved Aurignacian tool production by-products and a point from Unit F. Dates obtained on these eight samples would ideally provide not only dates for human occupations on human-modified bone but also dates for

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea, Fig. 6 Siuren I. Units F and E (1990s), Late/Evolved Aurignacian flint artifacts (**a**) *1–26*: Unit F artifacts. *1–9*: ventrally retouched Dufour microblades of Roc de Combe subtype; *10*: alternatively retouched Dufour microblade of Roc de Combe subtype; *11–18*: dorsally retouched pseudo-Dufour microblades of Roc de Combe subtype; *19–20*: bladelet "carinated" cores; *21–22*: carinated end scrapers; *23*: thick-shouldered end scraper; *24–25*: bladelet narrow flaked single-platform cores/"carinated burins"; *26*: simple end scraper/carinated (busked) burin. (**b**): *1–2*: Unit E artifacts. *1* bladelet "carinated" core; *2* bladelet narrow flaked single-platform core/"carinated burin"

both Micoquian and Proto-Aurignacian occupations at the rockshelter. The second group was composed of unmodified ungulate bones: four samples from Unit H, nine samples from Unit G, and four samples from Unit F; their dating was intended to verify the other dates. The dating results, however, did not entirely meet expectations.

Unit F can be considered as successfully dated. All three samples of bone tools were dated by Oxford and ranged between 28.2 and 26.6 ky BP. Of the four ungulate bone samples, three dates were obtained by the three laboratories (30.9–29.4 ky BP) and only one sample had collagen problems. The latter set of dates is somewhat older than the former; although considering dates only for level Fb1–Fb2, the time span is narrower: 30.9–27.8 ky BP. On the other hand, only two dates for the Aurignacian time range were obtained, from Beta Analytic, out of the 18 samples for Units H and G: c. 30.5 ky BP for Unit H and c. 28.0 ky BP for level Gb1–Gb2. Moreover, no samples from the five Micoquian and Proto-Aurignacian Unit G bone tools had sufficient collagen. Four dates for Unit H and level Gb1–Gb2 were too young: 22–13 ky BP. The other six samples had also collagen problems and were not dated.

There is thus a significant difference in dating results obtained from the 1990s and 2009–2011 bone samples between Unit F and Units H–G.

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea, Fig. 7 Siuren I. Late Gravettian flint artifacts. *1–2*: Unit D (1990); *3–11*: 3rd "excavation horizon" of upper layer (1920s) *1–4*: elongated blade/bladelet double-platform bidirectional cores; *5*: Gravette point with truncated base; *6–7*: shouldered/*pieces à cran* on bladelet and blade; *8*: backed bladelet microsaw; *9–10*: backed bladelets with elongated metric proportions and bidirectional scar pattern; *11*: simple flat end scraper

Below are data on samples with collagen problems, including those providing dates considered too young. Unit F has only 2 of 9 samples with collagen problems (22.2%), Unit G 16 of 18 samples (88.9%), and Unit H 4 of 6 samples (66.7%). Combined, samples with collagen problems from Units G and H are 20 of 24 (83.3%).

Such a high percentage suggests that something affected inner content of ungulate bone in Units G and H, causing most of them to have chemical content problems resulting in little or no collagen preservation. This may also explain the dates considered too young (22–13 ky BP). Moreover, with a few Aurignacian-like dates between 30.5 and 28.0 ky BP for Units H and G, statistically identical to the stratigraphically higher dates from Unit F (c. 30.9–29.4 ky BP for ungulate bones and 28.2–26.6 ky BP for bone tools), it is also possible to argue that the four Aurignacian-like dates (30.5–28.0 ky BP) do not

Siuren I Rockshelter: From the Late Middle Paleolithic and Early Upper Paleolithic to the Epipaleolithic in Crimea, Fig. 8 Siuren I. Epi-Gravettian and Final Paleolithic flint artifacts (**a**) *1–11*: Epi-Gravettian artifacts (1920s and 1990s excavations). *1–5*: non-in situ finds of Holocene humus sediments (1990s); *6–11*: 2nd "excavation horizon" of upper layer (1920s). *1–5*, *10–11*: backed bladelets with projectile damage; *6–9*: bladelet double-platform bidirectional cores. (**b**) *1–10*: The eastern Final Paleolithic "find spot" of 1st and 2nd "excavation horizons" of upper layer (1920s). *1–8*: simple flat shortened end scrapers; *9–10*: segments

represent a true age, being too young although not as recent as the four non-Aurignacian-like dates (22–13 ky BP).

Coming back to the uncalibrated AMS dates known in Europe for the Proto-Aurignacian with Dufour bladelets and Late/Evolved Aurignacian with Roc de Combe bladelets – c. 37–36 to 34–33,000 BP and c. 32–28,000 BP, respectively – recall that the two sets of Aurignacian units at Siuren I correspond well to these European Aurignacian industries. It is thus certain that Siuren I Unit F and its best archaeologically representative level (Fb1–Fb2) are attributable to the Late/Evolved Aurignacian with Roc de Combe bladelets, with six AMS dates around 30.9–27.8 ky BP, and corresponds well to the analogous European industry. On the other hand, the four existing "not too young" AMS dates for Units H and G (30.5–28.0 ky BP) do not at all fit into the known European Proto-Aurignacian chronology. Therefore, the suggestion of chemical content issues for the Units H and G ungulate bones appears more likely.

In sum, aside from the already proposed very late chronological position of Siuren I Proto-Aurignacian in Units H and G (c. 31–30,000 BP)

within the European Proto-Aurignacian as a whole (c. 37–36 to 34–33,000 BP), an alternative hypothesis is now proposed that the existing Siuren I AMS dates for Units H and G are too young for their real uncalibrated C14 age. As a result, the Siuren I Proto-Aurignacian could join the European Proto-Aurignacian not only on the basis of artifact similarities but also probably their chronology. Moreover, if this is valid, then the Micoquian in Siuren I Units H–G is also not too late, meaning that Siuren I can no longer serve as a strong argument for late survival of Micoquian Neanderthals in Crimea.

Liang Siyong

Phillip Grimberg
Department of Chinese Studies, Friedrich-Alexander-University Erlangen-Nuremberg, Erlangen, Germany

Basic Biographical Information

Liang Siyong 梁思永 was born on November 13, 1904, in Portuguese-occupied Macao as the second eldest son of political reformer and journalist Liang Qichao (1873–1929). Since his father was forced into exile after the premature end of the Hundred Days' Reform of 1898, Liang Siyong grew up in the Japanese harbor city of Yokohama where he received his primary education. After the downfall of the Qing Dynasty, he, together with is family, returned to China in 1913 where, from 1915 to 1923, he enrolled in classes at Qinghua University, preparing him for studies abroad in the United States (Wu 2002). There he

studied Archaeology and Anthropology with Alfred V. Kidder at Harvard University (Browman and Williams 2013). After graduating in 1930, he returned to China where he became a faculty member of the Institute of Archaeology at Academia Sinica's Department for History and Philology. From 1931 to 1937, he participated in and led numerous archaeological excavations in Northern China and at the site of the Shang capital of Anyang. In 1950, Liang Siyong was appointed deputy director of the Institute of Archaeology of the Chinese Academy of Sciences, serving for 4 years until April 2, 1954, when after a persisting illness he died of a heart attack. He was interred at Babaoshan Revolutionary Cemetery in Beijing.

Major Accomplishments

Liang Siyong is considered one of China's first thoroughly trained professional archaeologists and, together with Li Ji, father of Chinese archaeology, introducing the discipline to the country (Liu and Jones 2008). One of the first excavations Liang Siyong conducted in 1931 was at Angangxi in the city of Qiqihar, Heilongjiang province, where he unearthed Neolithic tombs and a number of wells from the Liangzhu culture, dating back more than 5000 years. Likewise, Liang Siyong's excavations of Longshan culture remains at Chengziya in Shandong province in 1934 represent a major breakthrough in the field, even more so due to his meticulous reports on the site, which were published as *Chengziya Site Excavation Reports* (城子崖遺址發掘報告) in the same year, one of the earliest scientific excavation reports ever to be published in China. Until 1937, the year of the outbreak of the Second Sino-Japanese War, Liang Siyong worked on the archaeological site of Anyang in Henan Province, where he unearthed tombs and burial structures in the ancient capital of the Shang dynasty. When in 1937 the majority of archaeological excavations ceded throughout the country, Liang Siyong retreated from the front lines of war to Changsha, Guilin, Kunming, and Lizhuang. After the founding of the People's Republic of China in 1949 and his being appointed deputy director of the Institute of Archaeology of the Chinese Academy of Sciences in the following year, Liang Siyong successively led further excavations in Anyang and at the sites of the Longshan and Yangshao civilizations, eventually sequencing the unearthed finds and establishing the first thorough chronology of China's earliest cultures.

His writing and areas of professional interest comprise – among others – publications on *Neolithic Pottery from the Prehistoric site at Xiyincun, Shanxi Province* (山西西阴村史前遗址的新石器时代的陶器), *Neolithic Pottery and Tools from Rehe* (热河查不干庙等处所采集之新石器时代石器与陶片), *Some Questions concerning Far Eastern Archaeology* (远东考古学上的若干问题), and *Longshan Culture – One of China's Prehistoric Civilizations* (龙山文化 – 中国文明的史前期之一).

Skeletal Biology: Definition

Douglas H. Ubelaker
National Museum of Natural History,
Smithsonian Institution, Washington, DC, USA

Brief Definition of the Topic

Human skeletal biology emphasizes the dynamic nature and complexity of the human skeleton. Research in human skeletal biology frequently focuses on human remains recovered from archaeological contexts. Topics of research generally relate to health, the relationships among ancestral populations as revealed in biological distance studies, and functional morphology through

related evaluations of behavior and use of the skeleton. Interpretations within the field recognize the mechanisms of growth and development, bone remodeling, sexual dimorphism, adult age changes, and population variation. More specifically, research foci can include skeletal evidence for disease, chemical analyses relating to diet, the growth and maintenance of bones and teeth, demographic reconstruction, trauma, cultural effects, biomechanical adaptation, and postmortem alterations. The term human skeletal biology is frequently used synonymously with the terms human osteology and bioarchaeology.

Smith, Claire

H. Martin Wobst
Department of Anthropology, University of Massachusetts-Amherst, Amherst, MA, USA

Basic Biographical Information

Claire Edwina Smith was born on July 15, 1957, in Sydney, Australia, as the second of three daughters, to James Alexander Smith and Annette (nee Jones) Smith. She spent her youth in Booragul, near Newcastle, NSW, with her working class parents, of Scottish and Irish background, inculcating her with empathy for the disadvantaged, tolerance toward others, valuing action rather than class or wealth, and respect for learning and progressive causes. Her interest in archaeology was inspired by a 1st year course in economic prehistory at the University of Newcastle in 1983 while enrolled in a degree in economics. It challenged her stereotypes about past and present Australian Aboriginal populations. She transferred to an Arts degree at the University of New England in Armidale, NSW, with a focus on Australian Aboriginal art, mentored by Mike Morwood and Jane Balme. She completed her Bachelor of Arts degree there in 1990, with First Class Honors and the University Medal with the thesis *Designed Dreaming: Assessing The Relationship Between Style, Social Structure And Environment In Aboriginal Australia*.

Her doctoral work, also with the University of New England at Armidale, focused on style in Aboriginal rock art, in theory and practice. It was based on extensive fieldwork with and for Aboriginal people of the Barunga region, Northern Territory, Australia, and mentored by Jane Balme, Betty Meehan, and Mike Morwood. It culminated in her 1996 PhD dissertation *Situating style: an ethnoarchaeological study of social and material context in an Australian Aboriginal artistic system.* Following an Australian Research Council Postdoctoral Fellowship, she was appointed to the faculty of the Department of Archaeology at Flinders University as Lecturer (1998), Senior Lecturer (2001), Associate Professor (2005), Professor (2010), and Head of Department (2012–2015). In 2016, she was appointed as Dean (Research) for the College of Humanities, Arts and Social Sciences. She has been the recipient of a Fulbright Postdoctoral Fellowship, hosted by the American University and the Smithsonian Institution National Museum for Natural History, Washington, D.C., in 2000–2001. She has held academic visiting appointments at Columbia University, Lock Haven University, Pitzer College, and the University of Denver in the USA, the University of Cape Town in South Africa, Kyushu University in Japan, and

Smith, Claire, Fig. 1 Claire Smith at Barunga, Northern Territory, 2012. With Danielle Bulumbara, Ester Bulumbara, and Nell Brown. Christine Camfoo and Wendy Willika in the background

the University of Newcastle, NSW, Australia. She is married to anthropologist Gary (Jacko) Jackson who has been an important collaborator in many of her research projects; they have one son (Jimmy) and reside in Blackwood, in South Australia (Fig. 1).

Major Accomplishments

Dr. Smith's scholarship is focused on the art, archaeology, heritage, present conditions, and deleterious outside interventions among postcolonial populations in general, and specifically the Aboriginal Barunga community of the Northern Territory, Australia. For details, consult Dr. Smith's full "Professional Curriculam Vitae" in the references. In addition, she has carried out fieldwork with Indigenous groups in India and Indonesia. Also among her research interests are rock art and the teaching of archaeology and cultural heritage (see for example Smith 2000), and how that teaching affects students, and also the future of Aboriginal populations and public understandings of the sophistication of Aboriginal cultures (e.g., she was the instigator of the following report: *A Past for all Australians: Archaeology and Australia's National History Curriculum,* submitted to the Australian government as input to the national history curriculum).

Very few people have been as intimately engaged with, and for, the people at the focus of their research as Dr. Smith. She has carried out fieldwork in the Aboriginal community of Barunga in the Northern Territory for more than 20 years now (e.g., Smith 2004) and with the Ngadjuri people in South Australia for more than a decade. Dr. Smith's goal is first and foremost to benefit Aboriginal communities and Indigenous communities in general. This is manifest in Dr. Smith's research and scholarship, in her teaching, and in her prodigious service and outreach.

She has been most visible internationally in her many roles in the World Archaeological Congress, particularly her 11 years as the President of the World Archaeological Congress (2003–2014), where she is the Immediate Past President. In her capacity for WAC, she worked to transform interpersonal relations in world archaeology. She has worked actively to democratize world archaeology by breaking down the "old-boy" English-speaking network that

controlled the field and increasing opportunities for Indigenous peoples and for archaeologists and archaeological students from low-income countries to share their knowledge with their peers and to obtain new knowledge in world conferences and through publications, including the *Encyclopedia of Global Archaeology*. She was the organizer and co-organizer of two WAC congresses, WAC-5 in Washington, D.C., in 2003 and WAC-7, at the Dead Sea, Jordan, in 2012. The latter conference provided substantial support for 440 participants from disadvantaged groups and low-income countries. In addition, she instigated many of WAC's new ventures including *the Global Libraries Program* (in support of disadvantaged institutions), *Archaeologists without Borders* (an international faculty exchange), *Archaeologies* (its international journal), and its web presence, and she reinvigorated its publication programs (with five new book series), its topical inter-congresses, and its championing of ethical practices within the archaeology and related disciplines.

Both in her academic and administrative functions, she is frequently voicing concerns in the public arena about policies deleterious to the archaeological record and its cultural custodians, particularly in postcolonial contexts. In Australia, and internationally, she frequently speaks out, and publishes academically and in popular media, about how governments and governmental and non-governmental organizations can interact with Indigenous populations in a culturally sensitive, fair, and just manner and how deleterious many public policies are toward Indigenous Communities. Most recently she is often asked to advise, consult, and help academic institutions, foundations, research museums, and Indigenous governmental bodies with that dimension of their work. Her research has been supported by grants from the Australian Research Council, the Australian Academy of the Humanities, the Fulbright Commission, Wenner-Gren Foundation, Australia Youth Foundation, Australian Institute of Aboriginal and Torres Strait Islander Studies, and Ian Potter Foundation, among others, and has generated considerable corporate support for the causes she champions.

Among her numerous publications, Dr. Smith has completed 12 books and more than 50 refereed articles and chapters (in English, and in Catalan, German, Japanese, and Spanish), as well as innumerable reports, conference papers, blog pieces, films, interviews, news releases, and more than 20 key note addresses at international professional venues (Argentina, Australia, Brazil, Canada, England, Japan, New Zealand, Nigeria, Portugal, Russia, and the USA). A number of these publications have been written with her close colleague, Dr. Heather Burke (Burke and Smith 2004, 2007; Burke et al. 2008, 2017; Domingo et al. 2007; Smith and Burke 2007). One of her most successful and far-reaching publication ventures has been her editorship of the *Encyclopedia of Global Archaeology* (11 volumes, 8,013 pages, 2,619 figures, 106 tables, 1,390 authors, and 1,625 entries). Its first edition, published in 2014, has received more than a quarter of a million downloads so far (Smith 2014).

But it is not just in her publications that Dr. Smith has helped to transform her profession. She has been a tireless worker behind the scenes, creating alliances, jumpstarting new cooperative research ventures, and helping along and mentoring young professionals, students, and people from disadvantaged populations. She has been one of the prime movers in the field of Indigenous archaeologies, in safeguarding Indigenous intellectual properties and cultural knowledges, and in the decolonization and empowerment of Indigenous heritage (See, for example, Smith and Wobst 2005). She is a passionate fighter for community-controlled research that increases opportunities; improves community control over community resources, knowledges, and patrimony; and leads to more sensitive and constructive treatment of community members by outsiders, be they academic, corporate, or governmental. She has worked ceaselessly to train students in these directions, to facilitate international and interdepartmental collaboration toward these ends, and to support young professionals from previously underrepresented populations, as in her support for the Closet Chickens (a mutual support group of Indigenous scholars and their friends). She also was a prime mover behind the

Smith, Claire,

Smith, Claire,
Fig. 3 Claire Smith, Gary Jackson, and extended family, 2017. Blackwood, South Australia

massive international cooperative research project *Intellectual Property Issues in Cultural Heritage* (funded by the Canadian Social Sciences and Humanities Research Council's Major Collaborative Research Initiatives program, 2008–2017), and she has organized a number of international conferences to further this agenda, including the Fulbright Symposium "Indigenous Cultures in an Interconnected World" (1997, Darwin, Northern Territory) (Smith and Ward 2000), "Cultural Heritage and Indigenous Cultural and Intellectual Property" (2006, Burra, South Australia), and "Cultural Heritage, Social Justice and Ethical Globalisation" (2007, Adelaide, South Australia).

Her many honors include the Jawoyn Aboriginal kin name, Lamjerroc, being given to her son Jimmy in 1990, and a number of prestigious teaching awards including the Carrick Award for Teaching (team category, held jointly with Dr. Heather Burke) and the Prince of Wales

Award, and she is a member of Flinders University's College of Distinguished Educators. She has been appointed to the Australian Research Council's College of Experts, elected to Fellowship in the Society of Antiquaries (London), and frequently invited to lend her insights and reflections as discussant to international symposia in anthropology, archaeology, Indigenous studies, heritage studies, and other fields. There are few if any people of her generation who have had a greater catalyzing influence on archaeology and related disciplines, to help them break out of narrow disciplinary molds and to direct them to projects that honor not only the past but also do justice and improve the conditions of the descendant populations who are the rightful custodians of that past today (Figs. 2 and 3).

Smith, Laurajane

Jessica Harrison
Department of Anthropology, University of Illinois Urbana-Champaign, Urbana, IL, USA

Basic Biographical Information

Laurajane Smith earned her B.A. and Ph.D. from the University of Sydney. She has held positions at Charles Sturt University (1990–1995), the University of New South Wales (1995–2000), and the University of York (2000–2009). At the University of York, she directed the M.A. program in heritage studies. She moved to Australian National University in 2010 and was an ARC Future Fellow there from 2010 to 2014. In 2014, she became Director of the then newly established Centre of Heritage and Museum Studies and coordinator of the Masters in Museum and Heritage Studies. In 2016, she became Head of the School of Archaeology and Anthropology.

Major Accomplishments

Professor Smith specializes in heritage studies. She is renowned for the concept of the

"Authorized Heritage Discourse" (AHD), which she featured in her 2006 book, *Uses of Heritage*. The AHD is the "dominant Western discourse about heritage. . . that works to naturalize a range of assumptions about the nature and meaning of heritage" (Smith 2006: 4). The AHD focuses on "things" and is dominated by "concepts of monumentality and aesthetics" (p. 4). Professor Smith is the editor of the *International Journal of Heritage Studies*, coeditor of Routledge's *Key Issues in Cultural Heritage* series, and the founder of the Association of Critical Heritage Studies, whose inaugural meeting was held in 2012. She was elected as a Fellow of the Academy of the Social Sciences in Australia in 2016 and was awarded a *Doctor Honoris Causa* from the University of Antwerp in 2018.

Smith, Mike

Alan N. Williams
Fenner School of Environment and Society, The Australian National University, Canberra, ACT, Australia

Basic Biographical Information

To my generation, Mike Smith seems one of the godfathers of prehistoric archaeology in Australia. Following in the footsteps of the Australian archaeology greats, like Rhys Jones, John Mulvaney, and Norman Tindale, Mike, a polymath by inclination, has been at the forefront of Australian archaeology debate since the 1980s. In over 30 years of research, Mike has been involved in research exploring the early colonization of Australia; the timing and composition of arid zone prehistoric occupation; the extinction of, and human interactions with, megafauna; the antiquity and mechanics of prehistoric seed grinding; and the late Holocene "intensification" debate. He has been instrumental in the application of new techniques to Australian archaeology, including geochemical provenancing of ochres, the use of thermo- and optically stimulated luminescence dating, and the routine inclusion of paleoclimatological and paleoecological analysis into excavations. Internationally, Mike is well

known within the South American and South African archaeological communities and is regularly invited to participate in conferences and research on both continents.

Mike grew up in Adelaide and much of his early career showed an ongoing interest in South Australia. His early fieldwork experience was pivotal and included Roonka, on the lower Murray, where he joined the museum's excavations in 1971 while still a school boy. Later he worked at Koonalda Cave with Sandor Gallus in 1973 and at Wyrie Swamp with Roger Luebbers, in 1974 prior to starting university. Both his B.A. (hons) and M.A. theses were undertaken at The Australian National University (ANU) and focused on sites in South Australia. His honors research involved a detailed faunal analysis of excavated materials from Devon Downs rockshelter, a 5000-year-old site located in the Lower Murray River. This site has a long history of investigation, originally excavated by Norman Tindale in 1930, who obtained some of first radiocarbon dates in Australia from this site in 1965, and most recently excavated by Mike himself in 1977 when he reopened part of the old trenches as part of his honors research. Mike's MA involved the systematic survey and investigation of Plumbago historic reserve (near Manna Hill) and was one of the first formal applications of probabilistic sampling techniques to an archaeological field survey.

At the beginning of 1980s, Mike took a job as the field archaeologist with the Northern Territory Museum, with a brief "to survey, record and excavate archaeological sites across the Northern Territory." Initially based in Darwin, Mike soon transferred to an office in Alice Springs and began a 30-year relationship with the prehistory of Central Australia. By the late 1980s, Mike had already surveyed and excavated a plethora of sites across region (Tjungkupu 1 and 2, Wanmara, Illarari kulpi malu tjukurr, Rrewurlpmurlpme Kweke, Kweyunpe 6, Urwemwerne, ORH16, Urre, Intirtekwerle, and Therreyererte), and importantly he had discovered one of the most significant sites in Australia – Puritjarra, a massive rockshelter in the Cleland Hills (Fig. 1). With the data from these sites, Mike completed a Ph.D. thesis (University of New England, 1988) and produced a number of seminal publications (see below), on the timing and pattern of prehistoric occupation of Central Australia. His ideas were critical in the formation of models on the colonization and abandonment of inland Australia during the Last Glacial Maximum. These studies were also the first to characterize the antiquity of seed-grinding processes in the desert and the first to explicitly explore the archaeology of a desert totemic center. Although his work highlighted the extent of economic intensification in the desert during the last millennium, Mike never formally

Smith, Mike, Fig. 1 (1986 Puritjarra) – Mike at excavations of Puritjarra Rockshelter 1986

entered the social intensification debates of the 1980s and 1990s preferring to decouple social and economic changes and empirically track these separately in his analyses.

Puritjarra was a key focus of Mike's research for several decades – with over 10 publications on the site in the last 20 years, each exploring a key theme in desert research. He has recently (Smith 2010) published the complete body of works on the site. It still remains one of the most comprehensive studies of an archaeological site in Australia.

Mike had met Rhys Jones, another key figure in Australian archaeology, on the Wyrie Swamp dig in 1974 and later sought out Rhys as an advisor and mentor on his Ph.D. panel. This developed into a strong partnership when Mike became a research fellow at ANU in 1989 and with Rhys and Bert (RG) Roberts undertook a number of nationally significant excavations at rockshelters in Arnhem Land, Northern Territory. These excavations, at Malakunanja II and Nauwalabila I, provided some of the earliest dates for the colonization of the continent (55 ± 5 ka). And even today, these sites still remain the earliest evidence of human occupation in Australia. This work in Arnhem Land – and that at Puritjarra – was the earliest deployment of luminescence dating at Australian archaeological sites.

Since 1996, Mike has worked for the National Museum of Australia (Canberra), as a Senior Curator and Research Fellow. While his main interests remained focused on Central Australia, the Museum provided a platform for broadening the scope of research to include other parts of the arid zone: looking at Genyornis nesting sites on the west coast with Gifford Miller (Fig. 2), mapping millstone quarries in the Strzelecki Desert, and using pack camels to explore the eastern margins of the Simpson Desert (Fig. 3). Key outcomes of his time at the Museum include his research (with June Ross) on the archaeology of the Glen Thirsty site, and the direct dating of Panaramitee style rock engravings in Central Australia (showing them to be much younger than previously believed); excavations at Lake Gregory (with Peter Veth and Jim Bowler) demonstrating early evidence of Aboriginal occupation; and the application of time-series analysis to explore human-environment interactions across dry lands in both Australia and South America.

Smith, Mike, Fig. 2 (2007 Kallakoopah) – Mike excavating a fragment of megafauna on the Kallakoopah River 2007

Most recently, Mike has brought the growing body of evidence from the arid zone together in a major synthetic book from Cambridge University, which has recently been published (Smith 2013).

Major Accomplishments

- Royal Society of South Australia's Verco Medal for outstanding contributions to the archaeology of Australia's deserts (2010)
- Contributing author to the Royal Zoological Society of New South Wales' Whitley Medal for "Boom and Bust" (2009)
- Australian Public Service Australia Day Achievement Medallion (2009) for outstanding performance relating to special projects or core duties
- Fellow of Society of Antiquaries (2007)
- Fellow of the Australian Academy of the Humanities (2006)
- Rhys Jones Medal for Outstanding Contribution to Australian Archaeology (2006).
- Member, National Committee for Quaternary Research, Australian Academy of Science (2010–)

Smith, Mike, Fig. 3 (2010 Simpson) – Over the years Mike (*right*) has become a keen cameleer. Inadvertently, this has given him far greater access into the interior of many of the deserts of Australia

Smithsonian Institution

David Tutchener
College of Humanities, Arts and Social Sciences, Flinders University, Adelaide, SA, Australia

Introduction

The Smithsonian Institution (See Fig. 1.) is a broad-based cultural institute situated in Washington, D.C., USA, and offers free entry to all visitors. It was founded by a bequest from James Smithson (1765–1829), a British scientist who left his estate to the USA to establish "at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge." Smithson's bequest amounted to more than 100,000 gold sovereigns (Smithsonian Institution Website 2012). Since its establishment as a trust by President James K. Polk on August 10, 1846, the Smithsonian Institution has become the world's largest combined museum and research complex, with 19 museums, the National Zoo, and 9 research facilities. The institutions of the Smithsonian house over 137 million objects and have over 7.4 million digitized objects (Smithsonian Institution Website 2012).

Definition

The Smithsonian Institution considers its mission as being instrumental in the increase and diffusion of knowledge. It also promotes its vision as: Shaping the future by preserving our heritage, discovering new knowledge, and sharing our resources with the world. The values of the Smithsonian are Discovery, Creativity, Excellence, Diversity,

Smithsonian Institution, Fig. 1 Image: Smithsonian Institution Website, 2012 Institution Building also known as The Castle (Smithsonian Institution Website, 2012)

Integrity, and Service (Smithsonian Institute Website 2012).

As a national body, the Smithsonian Institute covers a large range of cultural interests which is reflected in the large amount of museums and research centers that operates under its umbrella.

The museums and research centers that are incorporated as part of the Smithsonian Institution are listed below (Smithsonian Institution Website 2012).

Museums

- National Museum of African American History and Culture
- National Museum of African Art
- National Air and Space Museum
- Smithsonian American Art Museum
- National Museum of American History
- National Museum of the American Indian
- National Museum of the American Indian George Gustav Heye Center
- Anacostia Community Museum
- Arts and Industries Building
- Freer Gallery of Art
- Hirshhorn Museum and Sculpture Garden
- National Zoological Park
- National Portrait Gallery
- National Museum of Natural History
- National Portrait Gallery
- National Postal Museum
- The Renwick Gallery of the Smithsonian American Art Museum
- Arthur M. Sackler Gallery
- Smithsonian Institution Building (The Castle)

Research Centers

- Archives of American Art
- Conservation Biology Institute
- Environmental Research Centre
- Marine Station at Fort Pierce
- Museum Conservation Institute
- Smithsonian Astrophysical Observatory
- Smithsonian Institutional Archives
- Smithsonian Institutional Libraries
- Tropical Research Institute

Issues

While all the Smithsonian centers are funded in part from the original Smithson endowment, most of the financial support for the Smithsonian comes from the US Federal Government. In 2011 the Smithsonian budget request for the financial year 2012 requested over $850 million dollars (The Smithsonian Institution Fiscal Year 2012). To offset this cost, some funding bodies have questioned the free entry to the Smithsonian Institutions. However, free access by the general public was a condition of the Smithson bequest and is unlikely to change. These museums generate indirect income through the tourists they attract.

Modern museums function in a number of ways that manage to both preserve and absorb material culture while also disseminating culture and knowledge. This complex communication is managed through a number of different functions including acting as keeping places, functioning as research centers, and providing publicly accessible interpretation of collections in the form of exhibitions.

As a national institution, the Smithsonian has had a number of high-profile controversial exhibitions. The political views put forward in some exhibitions have caused some issues for the institution. These controversial exhibitions have since been used to help explore the role of museums in society and were later the subject of a study by the museum (Gavaghan 1995).

Enola Gay Controversy

A major controversy arose around the Smithsonian's National Museum of American History's exhibition of the Enola Gay, the plane that dropped the first atomic bomb that was used on humans at Hiroshima, Japan, during the Second World War was at the center of much debate. The planned exhibit caused controversy over the interpretation of the events and the historical significance of the Enola Gay (Gavaghan 1995). The proposed exhibition was accused of being anti-American propaganda (Sowell 1995). Subsequently, the exhibition was altered to show only

the plane and some film footage with minimal interpretation.

Life and Land Arctic Exhibition

The exhibition of photographer Subhankar Banerjee's work at the Smithsonian National Museum of Natural History was moved to a less prominent space at the institution under what is perceived as political pressure regarding climate change and oil drilling in Alaska. The artist was also asked to make several revisions to a book that was based on the exhibit, which included any reference to the Smithsonian. The author was told that the work was "just too political" (Bailey 2003).

Publications

The Smithsonian contributes and disseminates knowledge not only through its museums and institutions but also through a number of publications.

The Smithsonian is a monthly magazine, begun in 1974 that is aimed to cover a broad selection of topics including the arts, environment, sciences, history, and popular culture. The *Smithsonian* is the official journal of the institute that is based around communicating issues related to the Smithsonian collections and exhibitions.

The magazine *Air and Space Smithsonian* has been produced by the museum of the same name since 1986 and covers topics related to the advancement of technology related to aviation and space exploration.

The Smithsonian has its own *Online Encyclopaedia* that is divided into several sections including Art and Design, Science and Technology, History and Culture, and Kids Favourites.

Snow, Clyde C.

Luis Fondebrider
The Argentine Forensic Anthropology Team (Equipo Argentino de Antropología Forense, EAAF), Buenos Aires, Argentina

Basic Biographical Information

Clyde Collins Snow was born in Fort Worth, Texas, on January 7, 1928. He grew up in Ralls, Texas, where his father was a country doctor. From his early years, he followed his father, who introduced him into the world of science, disease, life, and death.

After graduating from junior college at the New Mexico Military Institute in Roswell, New Mexico, he received his Bachelor's Degree in Biology at Eastern New Mexico University, a Master's Degree in Zoology from Texas Tech University, and his Doctoral Degree in Anthropology from the University of Arizona.

In 1960, he joined the staff of the Federal Aviation Administration's Civil Aeromedical Institute (CAMI) where, over the next two decades, he conducted research in factors influencing survivability in aircraft accidents. In this role, he participated in the investigation of major air disasters, specializing in the identification of the victims. He also served as a pro bono consultant to medical examiners, coroners, and law enforcement agencies throughout the United States in cases involving the identification of skeletal remains. In this latter conjunction, he published the first scientific paper containing the term "Forensic Anthropology" (Snow and Luke 1970).

Major Accomplishments

Among his varied research projects was a long-term study of the Tarahumara Indians of northern Mexico who are among the world's most famous endurance runners. Its objective was to determine the factors contributing to their remarkable physical conditioning. It entailed a number of long trips to their remote villages in the *Barranca del Cobre* (Copper Canyon) over whose rugged terrain they run races of 24–48 h. He and his colleagues studied the physique and diet of the runners and telemetrically monitored their cardiac performance on treadmills and during actual races (Balke and Snow 1965; Snyder et al. 1969; Paredes et al. 1970). He also performed research on factors contributing to survivability such as age, sex, and seat location in major aircraft accidents (Snow et al. 1970) as well as anthropometric surveys of aviation-using populations (Snow 1965; Snow et al. 1975). The last commercial aircraft accident he helped investigate was the crash of an American Airlines DC-8 in Chicago on May 25, 1979 where he supervised the identification of the 273 victims. He also served for 2 years in the late 1970s on the panel of experts called to review all the evidence concerning the assassination of President John F. Kennedy for the US House of Representatives' "Special Committee on Assassinations" (Snow et al. 1979).

In late 1979, he retired from federal service and launched a second career as a full-time forensic anthropology consultant. As such, he was consulted on all skeletal cases from Oklahoma. He was also contracted by the Cook County Medical Examiner to examine all skeletal cases from Cook County which includes Chicago and its suburbs. One of his early Chicago cases was that of the notorious John Wayne Gacy who killed 33 young men and boys, burying 29 of them under his house. Along with the work in Oklahoma and Chicago, he was frequently called on cases in other states, including the "Green River" serial killings in Washington (Haglund et al. 1987) and that of Polly Klass, a 12-year-old girl kidnapped from her home in Petaluma, California, in 1993 and whose case attracted nationwide attention. He also used his skills in the analysis of remains found in historical contexts such as the bones of soldiers killed at the Battle of the Little Big Horn (Snow and Fitzpatrick 1989).

In 1984, his career took another turn when he was called to Argentina to help in the investigation of the thousands of Argentine men, women, and children who had been murdered during the military's self-proclaimed "Dirty War." These victims, the *desaparecidos* ("disappeared ones"), had been kidnapped, held in secret detention centers under torture and interrogation, and, finally, extrajudicially executed with their bodies being buried in clandestine graves scattered throughout the country. Between 1984 and 1990, he spent over 2 years in Argentina helping in these investigations, periodically returning to the USA to carry out his regular case work. During this time, he also recruited a small group of Argentine anthropology and medical students whom he trained up to carry out these investigations. In 1985, that group, the *Equipo Argentino de Antropologia Forenses* (*EAAF*) and Snow were called upon as expert witnesses to present some of their early findings in the trial of the nine members of the military dictatorship which resulted in the sentencing of three of them to life and another three to lesser terms. The trial was a forensic landmark since it was the first in which the testimony of scientific experts was used in a human rights case.

Later that year, he was called to Brazil where he headed the Simon Wiesenthal team, which along with other experts from Brazil, the USA, Germany, and Israel identified the skeleton of Josef Mengele, the infamous Nazi SS physician responsible for the deaths of thousands of Jews (Snow 1986).

In 1988, Snow and the *EAAF* were asked to come to Chile, which had its own *desaparecidos*. There they recruited and trained a team of Chilean anthropology students to help recover and identify the bones of the disappeared in their own country. Later, the Argentines, Chileans, and Snow journeyed to Guatemala and Peru where they formed similar forensic anthropology teams. By the early 1990s, the successes of these teams in their own countries had attracted international attention, and they were being asked by the United Nations and

international human rights organizations to help in the investigation of war crimes, crimes against humanity, and human rights violations in other countries.

He has presented his findings as an expert witness in courts and international tribunals at The Hague, Ethiopia, El Salvador, Peru, Mexico, and other countries. In 2006, he went to Baghdad where he testified as a prosecution witness in trial of Saddam Hussein for his genocidal "Anfal" campaign against the Kurds. His testimony was based on investigations of several mass graves that he and the Argentine, Chilean, and Guatemalan teams had excavated in 1991–1992.

Dr. Snow's statistical analyses of the patterns of disappearances have contributed significantly not only to the location and recovery of the desaparecidos but also on the overall modus operandi of repressive regimes (Snow and Bihurriet 1992; Snow et al. 2008).

Through his work in many countries from Argentina to Zimbabwe, Dr. Snow has helped develop forensic anthropology as a key discipline in the investigation of human rights violations. His work has also inspired many young forensic scientists in these countries, particularly Argentina, Chile, Peru, Columbia, and Guatemala. The endeavors of these teams have brought solace and healing to the families of the disappeared in over 30 countries by repatriating their missing loved ones and bringing justice to their oppressors.

Soares, Joaquina

M. Joaquina C. Soares
Museu de Arqueologia e Etnografia do Distrito de Setúbal, Universidade Nova de Lisboa, Setúbal/Lisboa, Portugal

Basic Biographical Information

Joaquina Soares (Fig. 1) was born in 1953. She obtained her Ph.D. in Prehistory from the Universidade Nova de Lisboa in 2011. The title of her doctoral thesis was *Social Transformations in the Third Millennium BC in Southern Portugal: The Settlement of Porto das Carretas*. She was an archaeologist in Gabinete da Área de Sines, from 1972 to 1988, and between 1988 and 2000, she worked in the Natural Park of Sudoeste Alentejano e Costa Vicentina. She has been director of the Museum of Archaeology and Ethnography of the District of Setúbal since 1974. Besides, she has been co-director of the archaeological review, *Setúbal Arqueológica*, since 1974 and editor of the cultural review, *Musa. Museus, Arqueologia e Outros Patrimónios*, since 2004.

Joaquina Soares lectures in prehistory and protohistory at the Universidade Nova de Lisboa and is an associate member of the Archaeological Center (UNIARQ) of the University of Lisbon.

Throughout her carrier, she has produced more than 100 publications.

Soares, Joaquina, Fig. 1 Joaquina Soares. Southwest Portuguese Coast, August 2012

Joaquina Soares and her husband, Carlos Tavares da Silva, were the first professionals working full time in field and theoretical archaeology in Portugal, starting with the project of the regional development of Gabinete da Área de Sines from 1972 to 1988 (Tavares Da Silva and Soares 1981).

Major Accomplishments

Joaquina Soares has directed and co-directed more than 100 archaeological excavations based on research projects and rescue programs over the last four decades. From 1997 to 2002, she worked on the largest rescue archaeological project of Southern Portugal, in Alqueva (dam of the Guadiana River). Along with Carlos Tavares da Silva and José Manuel Mascarenhas, she also conducted an archaeological and cultural heritage survey for the evaluation of the environmental impact of the dam construction in the phase preceding construction in 1984 and 1985.

Since 1975, Joaquina Soares had been dedicated to establishing a new concept of museology oriented to research and regional development in the Museum of Archaeology and Ethnography of the District of Setúbal, Portugal. Since 2003, she has promoted the first Portuguese regional network of museums, the Fórum Intermuseus do Distrito de Setúbal. Joaquina Soares combines research with social interactions and educational and information purposes. She has convened a number of conferences, workshops, and several international symposia, including the following: "Prehistory of wetlands. Landscapes of salt" held in 2011 and "Production and commerce of salted fish and fishsauces from the Atlantic Coast of the Iberian Peninsula, during Protohistory and the Roman Age" in 2004.

She has been the director of several research projects including the archaeological rescue project "Medida A" of the Alqueva dam, the urban archaeology research "Preexistencias of Setúbal," and the archaeological excavations on the pre- and protohistorical settlement of Chibanes in the region of Arrábida that is in the process of the

classification as a World Cultural Heritage by UNESCO.

Joaquina Soares has played a significant part in the development of Portuguese urban archaeology, mainly in the cities of Setúbal and Sines. With Carlos Tavares da Silva, she organized the first national congress on this matter: *I Encontro Nacional de Arqueologia Urbana* (1985). Her main research contributions in archaeology are in the areas of (I) cultural evolution of the Chalcolithic from Portuguese Estremadura, with Carlos Tavares da Silva; (II) identification of the first Chalcolithic fortifications from the III millennium cal BCE in Southern Portugal, with Carlos Tavares da Silva; (III) the Neolithization process in the Southwest Portuguese Coast (Soares 1996, 1997); (IV) the emergence of complexity in the III millennium cal BC on the Southwest of Iberia (Soares 2003, 2008a; Soares, and Tavares da Silva 1998, 2010a, b); (V) prehistoric salt exploitation in the Portuguese Coast (Soares 2008a); (VI) settlement strategy of the Middle Bronze Age of SW Iberia (Cultura do Bronze do Sudoeste); and (VII) urban archaeology in Setúbal (Soares 2008b).

Social Archaeology

Craig N. Cipolla
School of Archaeology and Ancient History, University of Leicester, Leicester, UK

Introduction

Societies and social relations have always garnered attention in archaeology. What has changed over the years are the ways in which practitioners define, prioritize, and integrate *the social* into their work. With the emergence of new forms of archaeology (e.g., processual, feminist, public), the significance of the discipline's social dimensions mutates and grows, the term "social archaeology" broadens in scope, and archaeologists' relations to non-archaeologists creep towards the forefront of our professional concerns. All of these trends stem from the complexities of working on the past in the present. The myriad of research projects and publications over the past decade, including the founding of the *Journal of Social Archaeology* in 2001, point to the growing importance and diversity of social archaeologies. In this entry, I offer a working definition for social archaeology, particularly as it pertains to the archaeologies of Native North America; however, I only do so with the acknowledgement that definitions are contextual and in a constant state of flux. In addition to this broad definition, I also provide some historical background and an example of social archaeology from a recent multi-sited research project in northeastern and midwestern North America.

Definition

The introductory editorial statement from the inaugural issue of the *Journal of Social Archaeology*, now a decade old, provides a fitting start for any definition of social archaeology in the twenty-first century. The editor succinctly noted the dual nature of social archaeology, stating, "Our challenge is to understand past societies in terms of their social contexts and lived experience while, at the same time, to remain cognizant of how the knowledge of the past that we produce is used in the present" (2001: 9). Like all archaeologies, social archaeologies maintain a general concern with those that came before. Their specific foci on past social relations, identities, and discourses – as seen in the material residues left behind by past peoples – often lead them in new theoretical directions and sometimes differentiate them from other forms of archaeology. It is, however, the second component of the editors' statement – the cognizance of archaeology's social impact in today's world – that truly defines social archaeology. Given this entry's placement in the *Political and Social* section of the encyclopedia, I focus solely on this important facet, which continues to both challenge and strengthen contemporary archaeology as a whole. In this sense, I see social archaeology as any form of archaeology that takes its potential impacts on the present and future just as seriously as it takes its interpretations of the past. Archaeologies so described range greatly in form. Issues of representation of the past for non-archaeologists, integration of descendent communities into archaeological research, and simply striving to improve the modern world with archaeological knowledge all encompass the spirit of social archaeology. While their specific research objectives vary, most forms of social archaeology concern issues of cultural heritage and the relationships between archaeologists and the many "stakeholding" publics that surround them.

Historical Background and Key Issues

I limit my discussion of historical background to four interrelated forms of archaeology: public,

Indigenous, postcolonial, and applied/pragmatic. I see each of these trends as the key contributors to contemporary social archaeology in North America.

Public Archaeologies

As defined by Charles McGimsey in (1972), public archaeology was originally conceived of as *archaeology by the state*. Since the 1970s, however, the scope of public archaeology has broadened to encompass any process of professional archaeologists – academic or state-funded – managing archaeological sites for the general "public" (Merriman 2004). This transition extended public archaeology to include public-interest archaeology in addition to publicly funded archaeology. Recent developments in the field deal with the public's direct involvement in the archaeological process. Shadla-Hall (1999: 147) defines this more recent version of public archaeology as "any area of archaeological activity that interacted or had the potential to interact with the public." Merriman (2004: 5) sees this new form of public archaeology as primarily concerned with ethics and identity: "Public archaeology is inevitably about conflict over meaning. . .This broader definition of public archaeology opens up a space in which to discuss not just archaeological products (such as educational programmes, museum displays and site tours) but the processes by which meaning is created from archaeological materials in the public realm." Two models emerged within this concentration in archaeology: the *deficit model* and the *multiple perspectives model* (Merriman 2004). The deficit approach seeks to inform (and perhaps convince) the general public of the relevance of archaeological research. The multiple perspectives approach suggests that Western academic knowledge is only one of many types of knowledge and seeks to incorporate the general public's views on the past. Within this spirit of public archaeology, practitioners question the relevance of their research for the communities it impacts (Mapunda and Lane 2004). Such considerations lead to new methods of incorporating non-archaeologists in various aspects of the archaeological process. This includes directly integrating community needs and interests into the research (e.g., Potter 1994; Cipolla 2013), a key component of other forms of social archaeology, including the many Indigenous archaeologies discussed next.

Indigenous Archaeologies

North American Indigenous archaeologies stem from the Indigenous rights movements of the 1960s (see Atalay 2006). Activists like Vine Deloria Jr. critiqued the discipline of anthropology for what he saw as its exploitation of Indigenous peoples. Indigenous communities critiqued archaeologists mainly for the ways in which they treated Indigenous burial grounds and human remains. This discontent eventually took the form of protests at archaeological sites and other types of social activism, which led (and sometimes forced) archaeologists to begin listening more closely to the concerns of Indigenous communities. In some instances, these early consultations and collaborations were legally mandated by federal and state laws passed in the 1980s and 1990s to help protect Indigenous rights to cultural heritage. In other cases, researchers such as Janet Spector and Larry Zimmerman readily embraced American archaeology's changing relationship to Indigenous communities, embarking in new forms of collaborative archaeology (McGuire 2004). Of course, these new approaches also drew influence from postprocessual archaeologies, which emphasized the fluidity of meaning and the importance of multivocality in understanding the past. Finally, Indigenous people began earning degrees in archaeology, further diversifying the discipline and pushing archaeological research in novel directions.

Although defining North American Indigenous archaeology is a difficult task (see Watkins 2000; Atalay 2006), many practitioners embrace the definition offered by George Nicholas and Thomas Andrews (1997: 3) as archaeology conducted with for and by Indigenous peoples. Among the many different forms of Indigenous archaeology are tribal archaeology, covenantal/reciprocal archaeology, and collaborative archaeology (Preucel and Cipolla 2008). One of the key variables in these different forms is the presence and role that outsides (non-Indigenous) play in the

research (cf. Bendremer and Thomas 2008; Silliman and Sebastian Dring 2008). Some argue for the importance of multiple cultural perspectives in such research while others see Indigenous archaeology as archaeology conducted only by Indigenous people for Indigenous people. It is best to consider the distinctions between the different types of Indigenous archaeology as differences of degree rather than kind since all share common interests in decolonizing methodologies (Smith 1999). Of note, it is the more diverse research strategies in Indigenous archaeology – those that incorporate multiple stakeholders (descendants, non-descendant community members, archaeologists) – that I see as firmly situated within the realm of social archaeology. I provide an example of such research below with my discussion of the Brothertown Archaeology Project.

Postcolonial Archaeologies

Postcolonialism refers to a broad series of critiques of the Western cannon by scholars such as Edward Said (1978), Gayarti Spivak (1988), and Homi Bhabha (2004). In its varied forms, postcolonialism defies definition in many ways. Yet, as Matthew Liebmann (2008: 2) explains, at the most basic level, "postcolonial approaches challenge traditional colonialist epistemologies, questioning the knowledge about and the representation of colonized 'Others' that has been produced in colonial and imperial contexts." These critiques and challenges focus largely on the ways in which colonial populations represent colonized peoples and their histories (Liebmann and Rizvi 2008). Although much of the literature focuses specifically on modes of representation in parts of Asia and Africa, North American archaeologists have begun to draw influence from postcolonial studies. For example, postcolonial theory shares common themes with many iterations of public and Indigenous archaeology discussed above. From the perspective of social archaeology, engagements with postcolonial theory offer archaeologists new means of detecting the Western biases embedded in their practices, creating new spaces in which to redress the injustices of colonialism and the appropriation of Indigenous histories by nonnative archaeologists.

Applied and Pragmatic Archaeologies

Jeremy Sabloff's (2008) recent volume, *Archaeology Matters*: *Action Archaeology in the Modern World*, provides many fitting examples of how archaeological research can be used to solve social problems in the contemporary world. Sabloff draws upon a diverse set of archaeological studies in order to demonstrate how archaeological data speak to contemporary issues of sustainability, warfare, urbanization, and more. Efforts that strive to use archaeological research to serve contemporary social needs are part of a broader trend in archaeology that Robert Preucel and Stephen Mrozowski (2010) label "the new pragmatism." Pragmatism is a broad philosophical framework that concerns itself with the effects that knowledge production has in the world. At the heart of their essay, Preucel and Mrozowski thus ask about the differences that archaeology can and should strive to make in today's world. Those archaeologists working in the spirit of applied and pragmatic research thus recognize that their work does not take place in a vacuum devoid of political and social implications. Simultaneously, they seek out new ways of using their work to solve problems in the present.

Case Study: Social Archaeology at Brothertown

The Brothertown Archaeology Project, a collaborative endeavor between the *Brothertown Indian Nation* and the author of this entry (Cipolla 2013), provides a fitting example of the ways in which archaeological research is becoming more social, incorporating the interests, sensitivities, and needs of more than just archaeologists. The project was designed to investigate Brothertown history and the legacies of colonialism in Native North America via the lens of collaborative historical archaeology. Since 2006, students, volunteers, and archaeologists, both tribal and nontribal, have worked together on an archaeological survey of the two Brothertown settlements, including an intensive survey of Brothertown cemeteries. For the purposes of this entry, I focus mainly on the implications of this work for the Brothertown Indians and other stakeholding publics. I begin with a brief summary of Brothertown history

before moving on to discuss the dynamics of social archaeology at Brothertown.

The Brothertown Indian community formed in the late eighteenth century when Christian factions of several Algonquian tribes from Rhode Island, Connecticut, and coastal New York moved west together in hopes of escaping the politics and corrupting influences of colonial culture on the East Coast. The community settled in central New York State for a time but relocated once again to current-day Wisconsin in the 1830s, where it remains centered today. Also important for this entry is the fact that the *Brothertown Indian Nation* was recently denied federal recognition after spending more than three decades preparing their petition. As I discuss below, archaeology has the potential to speak to social issues and needs such as this.

The research project embodies social archaeology in the sense that it resulted only from the interaction of multiple stakeholders. The collaborative process informed everything from research design and data collection to analysis and interpretation. For example, the project's focus on grave markers emerged through continued dialogue and interaction with tribal members. In fact, it was several tribal elders who first suggested that the research focus on their historic cemeteries. We continued discussing this possibility over e-mail in the months that followed, and I eventually visited a tribal council meeting to discuss the idea with the entire council. The *Brothertown Indian Nation* officially approved the cemetery research after we talked through our respective questions, concerns, and expectations.

In addition to shaping the research design, the collaborative process also informed my interpretations. My understandings of the contemporary Brothertown community influenced me to work towards a deeper understanding of colonial culture and Native American identity politics of the eighteenth, nineteenth, and early twentieth centuries. Like that of all communities making their places in the modern world, Brothertown culture is comprised of things, practices, and ideas that did not originate solely from within the Brothertown community. As the name "Brothertown Indian Nation" implies, however, the Brothertown Indians still make distinctions between insiders and outsiders. Within the shared cultural milieu of the modern world, the Brothertown Indian Nation has its own political organization and communal gatherings. Brothertown Indians recognize and celebrate their unique communal history and their ties to sacred sites. And members continue to work towards maintaining and preserving the community and its future, clearly demonstrated by their 30-year quest for federal acknowledgement. Along with my interactions with members of the Brothertown community and the tribal council, these general observations emphasized the need to move beyond the dichotomous tropes often evoked in archaeologies of culture contact and colonialism. The Brothertown community – past and present – is much more complex than the differences between Native American and European, colonist and colonized, or accommodation and resistance.

Recursively, the research also had practical effects within the Brothertown Indian Nation itself. The cemetery project collected information from a large portion of Brothertown grave markers, including their text inscriptions, imagery, and locations. This is particularly useful for those stones whose text inscriptions and imagery are beginning to fade away. This information is now preserved in electronic and hardcopy catalogues of the stones. A complete catalogue of the stones is available online for all members of the tribe, including those that no longer live in the vicinity of the historic cemeteries. Furthermore, a ground penetrating radar survey of the largest communal cemetery in Brothertown, Wisconsin, revealed the locations of several unmarked Brothertown graves. At least one member of the community is currently using this information to protect these once-lost graves, and the community may decide to formally remark these graves in the future.

Nonnative landowners and residents of both Brothertown settlements were also exposed to new perspectives on the places and spaces in which they currently live via the archaeological

fieldwork. The archaeology emphasized the Native presence in the landscapes of both Brothertown settlements. By interacting with archaeologists and members of the Brothertown Indian Nation in the context of the archaeology project, local landowners and residents were endowed with new senses of their everyday surroundings. More broadly, these experiences also help to challenge widely accepted stereotypes of "Indian-ness" and myths of the vanishing Indian. By confronting contradictions of these tropes, such as stories of the Brothertown Indians building the first Methodist Church in Wisconsin territory or constructing the very roadways that the residents drive on every day, the current inhabitants of Brothertown renegotiated their understandings of Native communities, past and present.

The case of the Brothertown Indian Nation's petition for federal acknowledgment provides one final example with which to consider the future of social archaeology. In December of 2009, Kathleen Brown-Pérez, chair of the *Brothertown Indian Nation Federal Acknowledgment Committee*, contacted me regarding the comment period following the publication of the *Office of Indian Affairs*' negative proposed findings against the Brothertown Indians' petition for federal acknowledgement. During this period, all interested and informed parties were invited to comment on the proposed findings, either supporting or refuting the claims.

As I reviewed the proposed findings, I was surprised to learn that my work had been misconstrued and misappropriated by the authors of the report. For example, the report (United States Department of Interior – Indian Affairs 2009: 12) states that, "Scholarly archaeological excavations, even of sites in Wisconsin, do not provide evidence that any historical observer made a contemporaneous identification of an existing Indian entity (Cipolla 2007)." While the bibliography of the report lists the source of this statement as "Cipolla 2007, Brothertown Indian Nation Archaeology Project," its origin remains unclear since the project had just begun in 2006 and no findings had been published by 2007. This experience served as a harsh reminder of archaeologists' responsibilities to the publics that they impact, intentionally or not. My responsibilities on site went hand in hand with my duty to point these fallacies out to the federal government.

Beyond the poor scholarship that went into the report, however, lies a much deeper issue concerning the relationship between archaeological data and the federal acknowledgment process. In direct contrast to the above quotation, the Brothertown cemeteries that we studied do indeed provide evidence of outsiders identifying an "existing Indian entity" in Brothertown. The spatial distribution of Brothertown and non-Brothertown graves in the cemeteries illustrates this point precisely. In the largest cemetery in Brothertown, Wisconsin, nearly all Brothertown grave markers sit in the southern half of the cemetery, which is known locally as the "Indian half." In other words, the Brothertown Indians consistently chose to bury their loved ones in close proximity to other Brothertown Indians, while Euro-Americans consistently chose to bury their loved ones in close proximity to other Euro-Americans. The importance of this pattern should not be understated. Brothertown Indians and Euro-Americans alike recognized the disparities between their two groups. Other cemeteries surveyed as part of the project provide similar examples of these historically recognized social and cultural distinctions. The fact that local Euro-American residents continue to refer to the southern half of the cemetery as the "Indian half" also suggests that it was known as such since the 1850s, when Euro-Americans and Brothertown Indians began sharing the landscape of Brothertown, Wisconsin.

Although these facts do not change the Brothertown Indian Nation's current political standing, they do highlight an under-explored social use of archaeological data (Mrozowski et al. 2009). One of the criteria that petitioning tribes must demonstrate in order to become federally recognized is that a large portion of its members lived together as an identified Indian community, distinct from other groups (Office of Federal Acknowledgement 2011).

Archaeological histories sometimes speak directly to these issues, particularly in cases where the communities in question did not speak and write in the English language as the Brothertown Indians did. In these cases, archaeological remains may represent core pieces of evidence, but archaeologists have yet to fully apply their work in such instances. This is just one direction in which archaeologists can further decolonize archaeology and partially redress the injustices of colonialism in the general spirit of social archaeology.

Future Directions

This brief discussion of North American social archaeology points to three interrelated directions for the future. First, archaeologists will continue to work towards incorporating multiple perspectives on the pasts that they study. This will take place as public and Indigenous archaeologies continue to flourish. Second, the discipline will continue to diversify as it attracts and hopefully welcomes more individuals from underrepresented groups into the field. In the spirit of postcolonialism, this diversity will lead to further scrutiny and correction of the discipline's imperialist roots and colonial biases (i.e., decolonization). Third, the expectation for archaeologists to produce socially relevant (applied and pragmatic) work will increase. Each of these trends suggests that archaeology is in an interesting state of metamorphosis from a discipline solely focused on discovering, classifying, and synthesizing a past for a small and homogenous group of professionals to one that articulates with the diverse social world of which it is a part.

Social Identity in Historical Archaeology

Heather Burke
Archaeology, Flinders University, Adelaide, SA, Australia

Introduction

Since the late nineteenth century, archaeologists have attempted to interpret widely recurring patterns of material artifacts in terms of a sense of distinctive identity. Linking such patterns explicitly to notions of social identity has become almost commonplace in contemporary historical archaeology in the last few decades, rendering it "the most pervasive theoretical term of the last few years" (McGuire and Wurst 2002: 85).

Definition

Psychologist Erik Erikson (1959) is generally credited with introducing the concept of identity to describe a person's psychological development over their lifetime: personal identity, despite periodic crises, is self-sameness, or self-stability, over time. Conceptions of the self, or the set of meanings that are tied to the self as an individual (personal identity), only arise in social interaction within the larger context of society; therefore, individuals are generally thought also to have social identities (Hogg 2006). Such a perspective connects identity with many other measures of social position around which social relations are organized, such as age, gender, occupation, religion, wealth, or education and the relative benefits and costs of each.

Historical and other forms of archaeology tend to approach the concept by assuming there is at least some potential to infer aspects of past social identities through material culture. There are two senses of the construction of social identity that are relevant here: the construction of it in the past, by people living their day-to-day lives in particular social and historical circumstances, and the reconstruction of it in the present by archaeologists relying on material proxies for this behavior (artifacts). A notion of personal identity (and, by extension, group identity) is not a property but a process; like the present, it always "is" and is never completed. Both are politically determined and are always in the process of being created; they cannot be reified as a category or a possession, even though archaeologists are forced to study them through the possessions of past people and the static patterns of material artifacts.

Historical Background

The study of social identity as a stand-alone goal of archaeology in the late twentieth and early twenty-first centuries has been spurred by four developments in archaeological theory and practice: studies of style as social strategy; the search for, and conceptualization of, agency in past human behavior; Marxist-derived critical archaeology that called for illumination of the origin of contemporary social circumstances; and its contemporary (although less overtly ideologically

positioned) derivative – the social justice movement in archaeology.

Deriving from structuralism, analyses of style in the 1970s and 1980s gave an explanatory lift to the concept of social identity by linking it to social, rather than merely physical, strategy. In a now well-worn formula, material artifacts were viewed as part of a strategic process and therefore used by different groups in different ways. Style functioned at the borders of groups to define difference to outsiders and within groups to signal similarity to insiders. In this sense, patterning was argued to have both a group and a personal identity dimension while still operating within the confines of what was socially and culturally possible.

While style brought a personal dimension to studies of social identity, agency perspectives, deriving as they did from sociology, deliberately sought to understand the conscious, creative, and collective practices of generic individuals within the limits imposed upon them by historical process and established social structures (Dornan 2002). Cultural theorists such as Pierre Bourdieu, for example, illuminated the constructed nature of taste to show how social reputation (and regulation) depends on struggles for prestige and position that employ material culture as markers. In the historical archaeological literature, agency is often presented as the local-level contrast to the global processes of capitalism, colonialism, or globalization. The central issues are the extent to which class, status, and other social axes constrain human behavior and to what extent people can operate outside these with material consequences, as well as the extent to which the construction of the individual (and notions of personhood and the self that tie deceptively easily to acceptance of Erikson's concept of identity) and class are in themselves ideological (Patterson 2005).

A strong Marxist strand in historical archaeology in the 1980s and 1990s focused discussion around issues of how social differences are given particular sets of meanings in the construction and discourse of social identity. Rather than treating identity as a categorical entity, we should use it as the lens though which to view society in a larger sense, since it is within this larger structure that important social processes (such as domination and resistance, power, class and inequality, or poverty and community building) are embedded. Notions of agency, society, and the individual should be problematized rather than reified and the many ways in which human action is embedded in social relationships exposed (Barrett 2000: 62).

The fourth and last strand is the trend within contemporary archaeological practice to contextually justify itself, often through the application of various "action" labels. The current literature abounds with adjectives reflecting both sides of the practice experience: the approach of the archaeologist (applied, engaged, ethically engaged, activist, advocate) and the involvement of some form of community (collaborative, participatory, embedded, public). This trend, and the strong social justice agenda it supports, has widened the search for social identity to encompass the material patterns of contemporary community politics often expressed through processes of cultural heritage management and to a lesser extent of the practice of archaeology as a middle-class activity (Matthews 2005).

Key Issues and Current Debates

The construction of social identity in the past was both a symbolic process and a slippery one; the reconstruction of it by archaeologists in the present is similarly complicated. Exploring notions of social identity highlights four key tensions within contemporary archaeology: the degree to which material patterning in groups of artifacts is a passive reflection or an active construction of past identity; the degree to which such patterning is produced consciously or unconsciously by the participants; whether or not it is ever possible to understand the individual as a social unit in archaeology, particularly for ordinary people; and the nature of the relationship between human choice and wider social structures.

Social identity operates at both the level of the individual and the collective. For every person, there will be facets of their individual identity that are important to their material choices, as well as

facets of their family and household identity. For the same individual, there may be a geographic community in which they live that influences their notion of identity (whether suburb, neighborhood, town, or village), various social communities of which they are a part (whether church, union, or social club), a work community (which can sometimes blend both the geographic and the social through the use of planned communities or company towns), and a range of other potential social categories that may well be beyond their individual control. While a person may be able to choose which church they belong to, for example, they cannot similarly choose whether or not to be female or black.

Trying to understand the slippery, contextual, and fluid nature of identity at any of these scales is the challenge of historical archaeology. Many historical archaeologists have used the notions of choice and autonomy that underlie the agency-social identity nexus as a means to reconstruct the lives of particular individuals as a way of personalizing the past. This has often been linked to the narrative turn in archaeology, so that connecting a person's identity to various facets of the material record from a site which they inhabited becomes a tale told of past lives. In historical archaeology, of course, there may be insufficient historical records from which to construct a profile of a particular person or household, and households as recovered archaeologically may or may not represent families, depending on the type and rate of occupancy for a particular building. At this personal level, studies have tended to focus on individual actors, despite the fact that agency as a theoretical paradigm disavows study of the individual per se (see Barrett 2000). Many Marxist studies would go further to argue that social identity should not be concerned with focusing on the individual, even with the best historical records, because our notion of the individual is itself an ideological concept. In this light seeing objects as the conscious creations of individuals or as part of the micro-histories of individual households is in fact dangerous (see, e.g., Johnson 1999: 128; McGuire and Wurst 2002).

At a community scale, archaeologists have focused on how identity is expressed through kinship networks, different modes of land distribution between generations, religion, notions of public and private space, or processes of community building and collective memory. A community can be as simplistic as a collective of individual households that may or may not be geographically bounded, a political construct, or a group of people linked by shared experience, daily interaction, and common class relations.

The ways in which material artifacts function as signifiers of identity in any of these contexts are equally as diverse. Many researchers have noted a distinction between genres of materiality, particularly the rapidly changing identity markers associated with the body (chiefly clothing, hairstyles, and language) and more stable markers, such as architecture, that endure and are able to convey a sense of permanence over the long term (see, e.g., Goodwin 1999; Mann and DiPaolo Loren 2001; Miller 1994; Parott 2005). Rapidly shifting markers are able to signal subtle shifts in political and social statements and in some contexts may have been more symbolically important than domestic goods contained within the private domain of the home (Steen 1999). The ideological value of more stable markers lies in their ability to retain patina (McCracken 1990), which verifies claims to status because it materializes longevity (Goodwin 1999: 144).

In between lie the many other material domains of domestic life. Historical archaeology, by necessity, most commonly approaches questions of social identity through the analysis of particular fields of material culture, such as the form and decoration of tablewares (e.g., Wall 1994); the political, gender, or class associations of clay pipes (e.g., Beaudry and Mrozowski 2001); meals and dining patterns (e.g., Shackel 1993); alcohol use (e.g., Reckner and Brighton 1999); choices in headstones and cemetery furniture (e.g., Mytum 2006); or the use of items of personal adornment (White 2005). The possession and use of such items were in many ways as important as their cost in terms of what they signified. Several studies of the identity constructs that accompanied the rise of gentility in the middle of the nineteenth century across the Western world (see, e.g., Young 2003) have noted how

closely the expression of social identity could be bound to the possession of behavioral knowledge (rules of behavior), as much as the economic ability to acquire specific material forms.

Future Directions

Social identity as a concept under which to cast various aspects of people's material choices is clearly very alluring to archaeologists. Linked to the strength of the concept of style in archaeology as a means to explain certain aspects of social dynamics and to various bases underlying contemporary archaeological practice that demands a more socially accountable archaeology, social identity has become a popular box in which to place many different aspects of past human behavior. At best it can become a means to highlight the tensions between individual subjectivity and the structuring constraints of broader social and historical circumstances; at worst it can become diffused beyond the point of serving as a useful analytical category. The challenge lies in understanding both correspondence and variation in material traces as more than just similarity or difference between groups and asking more difficult questions, such as how variation might be the result of, and create, social unity (Chenoweth 2011: 336–337), as well as its opposite, or how material similarity might mask social difference along other axes of identity. McGuire and Wurst (2002) remind us that shared identity is not necessarily the basis for shared action, any more than common goals derived from shared essential identities. The search for social identity hinges on seeing artifacts as parts of a process, not simply as finished end products, and on contextualizing patterning within a wider set of influences.

Social Memory in Archaeological Theory

Julia A. Hendon
Department of Anthropology, Gettysburg College, Gettysburg, PA, USA

Introduction

Social memory has been studied by historians, sociologists, psychologists, and anthropologists from many different angles. It has been described as a transdisciplinary concept with no single definition. While this varied interest has generated much insight, it has also made it important for researchers to be clear as to how they are approaching the concept. Archaeologists, not surprisingly, have been most interested in the relationship between social memory and the material world of ancient and historic societies.

Definition

Archaeological studies of social memory have centered on how monuments, buildings, objects, burials, and other material traces of human activity and practice create, reflect, or shape a group's social memory. Archaeologists have also been interested in how contemporary groups incorporate these material traces into their understanding of their history and identity.

Historical Background

Any discussion of social memory in anthropology must begin with Maurice Halbwachs (1877–1945), the French sociologist who wrote foundational works on memory in a social context. Originally published in France as *Les cadres sociaux de la mémoire* (*The Social Frameworks of Memory*, first published 1925) and *La topographie légendaire des évangiles en terre saint* (*The Legendary Topography of the Gospels in the Holy Land*, first published 1941), his ideas are best known to English-speaking scholars through the translations of Lewis Coser published as *On Collective Memory* (Halbwachs 1992). A third work, unfinished at the time of Halbwachs' death, *La mémoire collective*, was published posthumously in 1950. The original French edition was translated into English as *The Collective Memory*, but a more recent revised and corrected French edition has appeared and should be consulted (Halbwachs 1997).

Halbwachs argued for an essentially social approach to memory in contrast to existing approaches which saw memory as a function of the individual mind. He noted that people's memories are shaped by the social context in which they live and the social groups of which they are a part. What an individual remembers depends only in part on his or her lived experiences. For Halbwachs, more important were the events, relationships, places, and things that the collective group wished to remember. Central to his approach is the recognition that memory provides groups with a sense of identity, a sense of belonging, and a sense of history. *The Legendary Topography*, in particular, highlights a connection between place and memory, both in the way that places become memory cues and in the way that places become meaningful through their association with memory. One of Halbwachs' insights is that collective memory is not only social but can transcend the lived experience of any individual. In a striking illustration of this, he discusses how his first experience of London was shaped by his familiarity with Dickens and other authors as well as by conversations with friends. Halbwachs made it clear that memories are made, not just stored and retrieved, an insight since affirmed by social psychological research. He argued that the process of memory making was something that happened through or as part of social interactions. Consequently, people who interacted together

regularly were most likely to be involved in this process of memory making. Missing from Halbwachs' work is much of any discussion of conflict or how competing or contradictory collective memories might be resolved. In light of this, more recent work has preferred the term social memory, emphasizing its political as well as social aspects.

Paul Connerton has offered one way of understanding social memory in different types of societies that has been influential in archaeology because he dealt specifically with societies with and without writing (Connerton 1989). He also represents the move towards acknowledging the interplay between individual and social as a counterpoint to Halbwachs' emphasis on collectivities (reflecting Halbwachs' debt to Emile Durkheim). Connerton wants to find ways to recognize and study social memory independent of and in addition to what he calls inscription. The most familiar form of inscription is writing and the production of texts designed to transmit information. Connerton suggests that other ways of remembering exist. He focuses on commemorative ceremonies and bodily practices as forms of remembering that all societies make use of. Central to his argument is the efficacy of ritual in preserving and passing on memories that groups want to remember. This is a performative approach and a practice-based one – it is through performances of ritualized actions that people create a context for the passing on of traditions, beliefs, and what Connerton calls social habits. Bodily practices thus loom large in Connerton's model. These practices help produce what he calls habitual memory. In contrast to inscription, incorporation represents the bodily practices through which habitual memory is developed. Ultimately, Connerton's argument is evolutionary in that he sees a change over time from societies that rely on incorporating practices to those that rely on inscribing ones. This element of his model allies him with the notion that some societies have a sense of history and others do not. Nevertheless, his efforts to move beyond a reliance on texts have been fruitful for archaeologists, especially prehistorians or those interested in social memory created by social groups who, even in literate societies, did not typically inscribe their histories. Michael Rowlands provides one archaeological application of Connerton's ideas by looking at the role of monuments and burials in European prehistoric societies (Rowlands 1993). He argues against the usefulness of separating literate and nonliterate societies along an axis with inscription at one end and incorporation at the other. He also argues that certain kinds of material culture can result from acts of inscription. This latter point has been one that other archaeologists have emphasized, finding the distinction between inscription and incorporation too limiting. Landscapes, the ways they are shaped by people's actions, can be seen as a form of inscription and incorporation.

Another debate that archaeologists must address centers on the relationship between history and memory. Perhaps not surprisingly, many historians want to differentiate the two. Memory is individual, history is collective; memory is unreliable and mutable, history is as accurate as possible and subject to change through new information but not through new or different perceptions; memory is what nonliterate or non-Western societies have, while the literate Western societies have history – these are all aspects of the debate. Older theoretical perspectives in anthropology such as structuralism accepted this division between those with and without history as exemplary of hot and cold societies. The French historian Pierre Nora's massive project on *les lieux de mémoire* has been influential on archaeologists who have not always perceived the degree to which his concept draws on such structuralist framing. The rendering of *lieux de mémoire* as "sites of memory" in an early translation of his writing (a translation rejected by Nora in the later, more authoritative publication from Columbia University Press) was too tempting for archaeologists to ignore, and the term began to appear in discussions of social memory. However, for Nora, it is only modern societies, because they possess an historical consciousness, that create *lieux de mémoire*, foci of remembering that may be places but may also be songs, books, and other cultural products. Older societies, even "peasants," examples of groups without an historical consciousness, have no history and therefore do not create

lieux de mémoire. Instead, they create *milieux de mémoire* which allow the repetition of certain ideas and relationships through ritual but do not constitute history (Nora 1996).

Key Issues/Current Debates

More recent anthropological work on the subject has rejected the distinction between societies with and without a sense of history even as this work has endeavored to explore the different ways that remembering occurs. An example is the edited volume, *Making Alternative Histories*, which includes contributions from Latin American, African, and North American scholars assessing the interplay between anthropology, archaeology, and the politics of identity and heritage as part of their efforts to overcome the kinds of dichotomous thinking that reserves history to the West (Schmidt and Patterson 1995). In this endeavor, archaeologists have been joined by historians interested in the variability of social memory and its consequences for social interaction, political control, and cultural change. In the process, anthropologists have both undercut the idea that history can only take one form (that of specific events tied to particular dates) and that there is ever a pure or perfect historical narrative. Peter Schmidt, for example, examines the relationship between history, oral tradition, and memory in *Historical Archaeology in Africa*. In the process, he destabilizes the notion of prehistory or societies without history (Schmidt 2006). In *Houses in a Landscape*, Julia Hendon argues that alternative histories develop through the repeated actions of daily life and ritual at home that provide a counterpoint to the political histories produced by Maya rulers commemorated through monuments with hieroglyphic texts (Hendon 2010). These communities of memory provide localized histories tied to domestic places. Burying the dead at home and engaging in life-cycle rituals tied to the passage of time are two kinds of practices that took place in these domestic settings. These practices are ones that most archaeologists would recognize as ritual and likely to be productive of social memory. Hendon extends the ways that memory is produced, however, by arguing that domestic activities, which are ritualized in their own way, provide additional ways of making connections tied to particular places that endure over time.

Archaeologies of the Pueblo Revolt (Preucel 2002) and *History Is in the Land* (Ferguson and Colwell-Chanthaphonh 2006) explore the persistence of alternative perspectives on historical events by examining Native American (Hopi, Zuñi, Apache, etc.) expressions through oral tradition, art, and material culture of their views on their experiences with colonizers, Euro-American settlers, government officials, as well as with one another, ancestors, and other Native American groups. Archaeologists thus have solid support for applying social memory as a kind of history – or a history-making practice – to all societies. What is at issue is not whether or not a society has history or an historical consciousness but rather how that consciousness is expressed; how it relates to identity, politics, social relations, and even economy; and to what extent social memory is contested within society.

Recognizing memory as a social process has three important implications: First, as Adrian Forty and Susanne Küchler have argued, memory is as much about what is forgotten as it is about what is remembered (Forty and Küchler 1999). This is not a deficit but rather part of how societies use memory. Second, as *Houses in a Landscape* makes clear, it is more productive to focus on practices of remembering and forgetting rather than on social memory as a reified entity. Third (as already suggested by the first point), remembering and forgetting are inherently social and political. Social memory intersects with other aspects of society that archaeologists have long been interested in studying, especially politics, identity, and social relations.

Archaeologists working on literate societies, whether ancient Rome or the ancient Maya, have found that moving beyond the documentary record to a broader perspective on how social memory develops and what role it plays allows them to contextualize the statements of elites and leaders in the larger social setting. For those archaeologists working without documentary records, recognition of the ways that social memory can be inscribed in the material record has

provided insight into the kind of history that leaders, elites, or others in society wished to make their authority visible and permanent. Thus, in *Archaeologies of Memory*, editors Ruth Van Dyke and Susan Alcock divide the chapters between those studying societies with text and those studying societies without (Van Dyke and Alcock 2003). Despite the obvious differences between the two groupings, what is striking is the degree to which the contributors converge on a set of things to study and agree on the role of social memory. Alcock's earlier work on social memory in the classical world, *Archaeologies of the Greek Past*, makes a strong argument for the value of studying social memory from material evidence as well as from textual sources (Alcock 2002). Her three case studies demonstrate how landscapes and monuments become enmeshed in the construction of group identities.

Landscape, burials, and monuments constitute three of the commonly invoked material traces around which social memory coheres. Thus both the edited volumes, *Social Memory, Identity, and Death* (Howard 2003), and *Archaeologies of Remembrance* (Chesson 2001), take the practice of burying the dead or other kinds of rituals related to the dead as emblematic of how groups use social memory to create identities that continue over time, connecting the living and the dead. The recognition that it is the living who decide how to bury the dead is central to the case studies in these volumes. Rather than seeing burials as some fixed and essential reflection of status or individual identity, the contributors consider how mortuary rituals allow the living to reinforce or emphasize those aspects of identity important to their own identity and relationships.

Landscapes have been studied as complex palimpsests, using Barbara Bender's term, of deliberate and habitual actions that shape the land itself and people's understanding of their relationship to the world around them (Bender 1998). The degree to which places, monuments, and buildings – in other words features of the natural and build landscape – persevere beyond the individual human lifespan means that they provide solid, substantial anchors for remembering, a point first made by Halbwachs in his discussion of religious landmarks in Jerusalem and other Holy Land locations. It is this ability to seem permanent that led Rosemary Joyce and Julia Hendon to argue that Connerton's concept of inscription was too limited if confined only to documents or texts (Joyce and Hendon 2000). They used placemaking in the lower Ulua Valley of Honduras to exemplify how long-term relationships and meanings can be inscribed on a landscape. Unlike Rowlands, though, Joyce and Hendon also argue that incorporation and inscription can merge in the meanings ascribed to landscapes. Patricia Rubertone makes a similar point in *Archaeologies of Placemaking*, bringing the process of inscription into the present through her focus on the tension between public commemoration or acknowledgment of a Native American presence in North America and how those commemorated view these monuments (Rubertone 2008). Here, as with *Archaeologies of the Pueblo Revolt*, *History Is in the Land*, and Martha Norkunas's *Monuments and Memory* (Norkunas 2002), about preservation efforts in Lowell, Massachusetts, the political aspects of social memory become part of present-day attitudes and play into decisions about how to represent that past in public or official contexts.

Inherent in many of the treatments of social memory making discussed so far has been a focus on ritual. Connerton made this explicit in his discussion, arguing that rituals are well suited to remembering because they are less subject to change. Archaeologists have both embraced the importance of ritual and questioned it. Richard Bradley has pointed to its importance and has used evidence of ritual action to understand the construction of social memory in European societies that lacked writing (Bradley 2002). Nevertheless, as Hendon as noted, too strong a reliance on rituals runs the risk of neglecting the history-making potential of daily life at home or away. A more productive approach is that taken by Hendon and the contributors to *Memory Work: Archaeologies of Material Practices* (Mills and Walker 2008). Without rejecting the importance of ritual, *Memory Work* and *Houses in a Landscape* focus on *practices* through which people created or deposited or modified places and things. Some of these practices fit a standard anthropological definition of ritual but not all.

The focus in both books is on the depositional practices that leave behind traces of actions designed to inscribe on the landscape aspects of identity, significant action, and in the process memories. By shifting the focus to practices, archaeologists have a way to continue to acknowledge the importance of ritual while also recognizing the potential significance of all actions and practices in remembering and forgetting. Social memory does not develop only through specific kinds of actions. The decision to foreground or privilege certain kinds of action or practices is in fact a political one, on the part of either people in the past or researchers in the present.

International Perspectives

The study of social memory has become common throughout the discipline of archaeology. Specialists working on prehistoric, ancient, and historic societies in many different geographic regions have incorporated the concept into their research. As the references and suggestions for further reading at the end of this entry suggest, Mesoamerica, the Andean region, Africa, Mesopotamia, Europe, and North America have been particular sites of social memory research, but the concept is even more widespread than this list suggests. Issues of heritage and identity are not limited to the Americas, and historical archaeologists in particular have addressed the controversies and values surrounding the construction of social memory in many postcolonial contexts. Although this review has emphasized the English-language literature, scholarship on social memory is not restricted to Anglophone archaeologists or to those publishing in English. Latin American and European archaeologists have contributed to the discussion of *la memoria social or la mémoire social* as well.

Future Directions

At this point social memory is well integrated into the conceptual framework of many contemporary archaeologists. Studies of social memory-related practices will continue to appear. Like such other important social facts as gender, power, hierarchy, and heterarchy, social memory should also become incorporated into more general or broader studies as part of what one needs to address if one wishes to understand how past societies made sense of the world in which they lived. Debates about whether or not a group has social memory are no longer enlightening. Likewise, debates over the veracity of texts, oral traditions, or the material practices through which social memory is produced and reproduced are of less interest. What needs to be addressed are the how and why of remembering and forgetting in specific social and historical contexts.

Social Movements and Archaeology

Ivana Carina Jofré
Comunidad Indígena Warpe del Territorio del Cuyum, Colectivo de Arqueología Cayana, Escuela de Arqueología, Universidad Nacional de Catamarca, San Fernando del Valle de Catamarca, Catamarca, Argentina

Introduction

With the aim of presenting a contemporary and yet generalized definition of archaeology in relation to social movements, it is necessary to situate both as two fields with origins that are dissimilar,

but not necessarily opposing, and increasing in mutual collaboration. The first field, archaeology, is found to be historically bound to the production of academic knowledge around the discipline of the past, usually in agreement with the political interests of the Administrators of the colonies and the modern Nation States. The second, social movements, is linked to emerging collective action and is about eminently practical orientations aimed at broadening the areas of participation in decisions of collective interest. And as such, it primarily contains and promotes, over all, a political meaning.

Archaeology has produced collaborative works with social movements that even gave origin to specific lines of work within the discipline; this is the case, for example, with Feminist Archaeology (e.g., Colomer et al. 1999) and Gender Archaeology (e.g., Gero and Conkey 1991; Gilchrist 1999) which were originally characterized by their questioning of the male-centered standards involved in the production of knowledge within the discipline and the cultural and politically construed character of essentialist categories employed by the discipline to approach the explanation and interpretation of the subject and data of the past. Such work renewed discussions of the subjective position of archaeologists in academic production and their political and social stakes within the social movements in their own societies.

But it was the postcolonial theorists who focused the attention of the discussions on the predicament and political role of the intellectuals starting from the subjective position of the researcher; they based the problem of discursive displacement that the new academics and professionals coming from the old colonies were beginning to produce at the interior of the Humanities and Social Sciences. As Castro Gómez and Mendietta (1998) aptly explain it, the postcolonial theories produce knowledge in a kind of "discursive translocation" starting from a crisis that is produced at the core of these theories. However, the postcolonial intellectuals' realization of their own hegemonic position, in academia and outside of it, necessitated the review of the paper that anticolonial and Third World narratives assigned historically to "critical intellect," a situation that also demanded the redefinition of the relation between theory and practice (Castro Gómez and Mendietta 1998). It is in this way that postcolonial theories, also in archaeology, were characterized by the appearance of these tensions of identity belonging to an era in which local knowledge interacted with global projects in a dynamic and changeable way, blurring the cultural frontiers.

Bound to political outlines of a postcolonial nature, the so-called Indigenous Archaeology, currently considered a subdiscipline within archaeology, was also developing during the last decades of the twentieth century as part of the agenda of work of various archaeologists especially in countries such as Australia, the United States, and Canada, and in response to the demands put forth by the movements of communities and nations of Indigenous peoples. George Nicholas (2008: 1660) has referred to Indigenous Archaeology "as a form of archaeology where the Indigenous people are involved in the care and excavation of the cultural and corporal remains of their ancestors." However, this definition does not specify a line of work, not exclusively of Indigenous subjects, and that in a broader plan it hopes to be a project of decolonization of the practice of archaeology the world over. That is to say, it deals with a redesign that occurs at the interior of the discipline of the ethical and political role assumed by archaeologists and the form in which they plan their research in relation to the communities with whom they interact (e.g., Ucko 1989; Watkins 1999, 2001, 2003; Endere and Curtoni 2003, 2006, 2007; Smith and Wobst 2005; Atalay 2006a, b, 2007a, b; Smith and Jackson 2006; Smith and Burke 2007; Burke et al. 2008; Bruchac et al. 2010; Jofré et al. 2010a; Nicholas 2010).

The Colombian archaeologist Cristóbal Gnecco (2008) referred to Indigenous or Native Archaeologies as "archaeologies of local meaning" or "reactionary political practices" to the dominant cultural rationale. These new archaeological practices, closer to emerging social movements, promote and contribute to the construction of plural areas and are also, as Alejandro Haber (2008) sustains, displacements that the discipline

carries out to rise up in its colonial relation with the local communities. Pedro Funari (2001, 2004) has for his part adhered to the denomination of "Public Archaeology" to refer to these new pluralisms that occur in the field of scientific archaeological practice. He understood them as horizontal expressions and not hierarchical in difference, in terms of political economy like interpretation, that which implicates archaeologies with publics, protagonists, and broader purposes. These collective, public, and plural archaeologies can be conceived "as a coproduction in which the involved sectors collaborate, learn and produce history together, although not without productive conflict" (Gnecco 2008: 101).

Key Issues and Current Debates

International View: Archaeology and Social Movements in South America

To speak of archaeology and social movements, we should refer ourselves to the type of relation initiated between this discipline and the conflicts, interests, and orientations that these social movements pose and or manifest. An always complex and delicate field is that of the processes of patrimonialization in which archaeology is generally implicated as the controlling agent of the State. However, as suggested earlier when I referred to the Indigenous Archaeology, there currently exists a number, fortunately ever-growing, of collaborative works between archaeologists and sectors of society historically passed over in its rights, such as the Indigenous peoples or communities of decedent Indigenous population that acknowledge other types of meanings and values in the remains of the past. In these cases, the archaeological patrimonialization of the remains of the living memory of a people can become the imposition of foreign values on these communities and the exposure can become the expropriation by means of legal mechanisms of intervention operated by state agents, multilateral organizations, private companies, etc. They offer an interesting debate with respect to distinctive archaeologists of the South closely reflecting the implications of the processes of patrimonialization in different ex colonial countries of the world (*Diálogos del Sur* 2007). As for example, Zimmerman contends:

> Academic archaeology should learn to live in the real world and acknowledge that not everybody considers the past public heritage. Many people that are not archaeologists consider archaeological heritage as their own, not as belonging to archaeology; they want to protect it and interpret it themselves or, they strongly wish for it to be left alone (*Diálogos del Sur* 2007: 14).

Patrimonialization is an "act of memory" in which the forces of political conflicts are implicated, whose finality is the production of a significant heritage for the State, and through which determined social actors try to conserve particular memories of their past. For this motivation, the processes of patrimonialization are accompanied by emerging processes that can be called contra-patrimonialization. These last processes would be something like the contra-hegemonic powers produced in and for the hegemonic conflicts for the definition and establishment of the heritage of a people or nation. From my own experience as an Indigenous archaeologist working in the Republic of Argentina, I offer a case for analysis as a current debate, in which I try to demonstrate how we can think of possible relations between archaeology and the emerging social movements from the perspective of patrimonialization. The case I refer to is, of course, subject to the local peculiarities, but it serves as an example of a situation largely generalized in South American countries today.

The Political Role of Archaeological Heritage in the Demand of the Social Movements of Citizens Assemblies in Argentina

The change of the capitalist accumulation model in Latin America during the last decades of the twentieth century witnessed the expansion and intensification of a project tending toward the control, extraction, and exportation of natural goods (Svampa and Antonelli 2009). This emerged in the 1990s at the height of the era of the politics of privatization, when the majority of South American countries started a profound reform of their regulatory frameworks to benefit the establishment of transnational companies in

this region of the world (Svampa and Antonelli 2009). These constitutional and legislative reforms that institutionalized the self-exclusion of the State as a productive agent were stimulated and supported by international organizations (World Bank, Inter-American Development Bank, among others). In this way, Argentina, as in other places in South America, awarded full exclusivity to the private sector to exploit the (inaptly named by capitalist jargon) "natural resources" (Buiteaar 2001; Power 2002; Schiaffini 2004; Clark and North 2006; Ortíz 2007; Bebbington 2007; Solanas 2007; Svampa and Antonelli 2009). In these conditions, the Nation State put into action, under the proposed expansion of a national development model, the suppression of the local economy, consistent in the exploitation of the so-called non-renewable "natural resources" by transnational actors and local partners (Ortíz 2007; Solanas 2007; Svampa and Antonelli 2009).

Only in the province of San Juan (located in the mountainous zone of central eastern Argentina) were more than 20 mega-mining projects put into place (Giovannini et al. 2009) which can be found in different phases of work; among these, the two most important projects belong to the transnational company *Barrick Gold Corporation*. This company possesses the Mina Veladero project, active since 2005, a deposit of gold and silver located more than 4000 m above sea level in the Andean mountain range in the Departments of Iglesia and Pascua-Lama; the first binational mega-mining project which is also located in the high Iglesian mountain range on the Argentinian side. Another important mega-mining project for the extraction of silver and copper, known as Gualcamayo, is located in the vicinity of the river of the same name in Jáchal. These grand-scale exploitation projects are located near the natural glacier springs and the former mountain pathway used intensely at one time by the communities for cross-mountain activity like shepherding, trafficking of products, and communication that served as local modes of social, cultural, political, and economic integration with varying levels of autonomy throughout local history. The archaeological remains of these distinct territorial occupations that were happening throughout history in this geographical space allow us to today account for the existence of multiple "places of memory" (Nora 1984), or significant spaces of the collective memory, coexisting by way of palimpsest in which they impose long-standing historic meanings (Jofré et al. 2010b).

These transnational extractive economic projects transform the state geographies of inclusion and exclusion. The city biases, and other identities subordinated to the construction of territorial sovereignties, begin to be reconfigured giving way to processes of confirmed supranational integration (that involves as many processes of inclusion as those of exclusion) for the Binational Argentine-Chilean Pact.

The symbolic conflicts that give transnational or supranational context call on forces of homogenization as well as heterogenization, and they attend to the processes of re-territorialization of the productive processes of flexible capitalism implicating, at the same time, de-territorialization of the social and cultural memory in which local identities have been constituted historically (Jofré 2013). On this point, scientific narratives like those of archaeology play a fundamental role in the installation of these true regimens in which the politics of knowledge oriented to the details of the appropriation-expropriation of territories is imposed (Jofré et al. 2010b).

Over a certain period, archaeological heritage came to be integrated within the heritage of the people threatened by an eminently extractive economic model with high environmental and socio-cultural impact, above all, without social license. The increasing installation of mining undertakings in the rural areas with greater archaeological sensitivity in provinces, like San Juan, Catamarca, Tucumán, Salta, Chubut, and Neuquén, generates conflicts that, in some cases, have had greater visibility for their capacity to permeate in social tactics, achieving diffusion in the public media sphere. The case of "Proyecto Navidad" in the Department of Gastre of the Province of Chubut (Claps 2010; Gómez Otero et al. 2010) is a paradigmatic example since, from being located in an Indigenous Community, it had to oppose the

distinct logics of territorialization of the social and cultural memory of communities with more than a millennium in the region.

In response to this situation of territorial pillaging instigated by their own State, a heterogeneous sector of the population began to organize social movements of protest throughout the lower part of the country, a new form of assembly. The Citizens Assemblies are new self-convened forms of social organization of citizens that began to crystallize in Argentina from the year 2001. It deals with a process of collective reproduction about the current forms of emancipation; its immediate antecedent is represented by the "picketing groups" who, like the Citizens Assemblies, brought to the public table new forms of social protagonism at one time dismissed from the traditional political process (Colectivo Situationes 2002). Currently, the self-summoned Citizens' Assemblies of neighbors have diverse location and demands throughout the length and breadth of our country, among these stand out the Assemblies that struggle against the undertaking of agricultural businesses, paper mills, and megaminers. In short, these social movements have been adapted through new forms of discussion, coordination, and collective thought by all who have decided to organize themselves outside of the classical political forums. Something very interesting about these new social organizations is that they crystallize new ways of constructing social links and they are above all active in the demands for work, food, and rights. It could be said that their struggle is for justice and social change, and in this sense, the Citizens Assemblies are a place of practical research because knowledge and new forms of sociability are being created there (Colectivo Situaciones 2002).

Among the claims carried out by the new organizations of the Citizens Assemblies in Argentina, archaeological heritage was notably missing in the initial concerns of these social movements, but with the flow of these in the last few years, they began to incorporate the concern for the remains of the living memory of the people more and more in their demands for the defense of the water and the land. This currently affects the momentum of the emergence of contra-patrimonialization processes to repel scientific discourse and de-historicizing "places of memory" considered "sacred" to Indigenous peoples. This type of learning began to be more evident within the Citizens Assemblies of places such as Catamarca, San Juan, Tucumán, Neuquén, and Chubut, where these social movements began to interact and work well with the claims of Indigenous peoples that were being newly threatened and stripped of their ancestral territories.

Claims for the return of the bodies of our ancestors, taken to museums by university or state commissioned archaeologists, to the land, today reignites the struggle for the land in a broader sense of the term, as a way of reaffirming our identities in a place belonging to history. Clearly, this discourse promotes a political sense of territory, potentially performative of the social relations of domination that made the establishment of highly questioned transnational projects in the region possible, and the exacerbated concentration of lands in the hands of agricultural industry landowners in Argentina.

In the same struggle for land, only a few months ago, in the province of San Juan, the Indigenous Community of Warpe of the Cuyum territory, in collaboration with the cosignatory of archaeologists and social organizations, presented a petition to the National University of San Juan soliciting the application of the recently regulated National Law 25.517 that protects and regulates the right of the Indigenous peoples to demand mass return of human bodies considered to be antecedents and ancestors. Today these bodies are in the hands of a museum dependent on this university, with motives of research and public exhibition in display cabinets and refrigerated coolers. This document states a demand for the return of the bodies to the land, avoiding the possibility that the State, by means of science, would implement the return of these human bodies as a hidden way of exchanging "bodies for land." From the original world view that territory comprises of an encompassing vision of the land and the beings that inhabit it: "We are land, the land is everything, the land is our life." Under this kind of statement, our Indigenous leaders question not only the universities but also the President of the Nation, Cristina Fernández de Kirchner, as previously done on May 20, 2010 (with motive of

the Bicentenary of the Argentinian Nation). During that opportunity, the leaders that mobilized a mass protest of 20,000 people asked the President for concrete solutions for the evictions suffered by the Indigenous Communities throughout the length and breadth of the country: in short an historic reparation to meet the demands of the people dispossessed by the Nation State.

This petitionary case carried out by the warpes communities in San Juan, like other similar cases that are happening in our country, highlights the political symbolism that the bodies of ancestors acquired in the field of these social conflicts that face different ontologies of the relations between communities and their lands, at the same time that it also redefines the place that archaeology holds in these movements (Jofré 2010).

Conflicts like those on which I have commented here raise meanings that are incompatible, and sometimes juxtaposed, from the traditional, the modern, the local, and the global, resulting in disastrous consequences due to the imposition of new forms of extreme, disproportionate, and limitless exploitation of the environment and the irreversible destruction of the local ways of life. As retaliation of this situation of extreme injustice, "Water is worth more than gold," in the case of the Republic of Argentina, represents the current determination of the communities and people that is similar to other sectors of South America, where they are rising up against the supposedly generous promises of the extractive models of global capitalism, imposed with the compliance of the serving government.

Future Directions

Possibilities of the Collaboration Between Archaeology and Social Movements: The Right to One's Own History

Today, the common point of intersection between archaeology and social movements is a work of innovative coproduction originating in the context of decolonization projects of the archaeological discipline. In countries in South America, for example, these new collaborative works markedly began in the 1990s as a response to the profound change in global world order connected to the processes of expansion of flexible capitalism. These processes began to take shape in the 1970s, and recently, in the 1990s they acquired a social visibility, crystallized in new conditions of planetary coexistence known now as: transnationalism, globalization, situations directly related to a new type of neoliberal governability (Gordon 1991). This last condition was characterized by the "rolling back of the State" or privatization of responsibilities through the outsourcing of key social services, and with the consequent concession of regional autonomies as part of an adjustment to new dependency models.

The deep undercurrent of these new scenarios of conflict in South America is the "dispute for land." These countries with colonial history today are threatened by tyrannical and violent endocolonialisms supported by their own Nation State acting in service of the private transnational capitals mobilized by the economic monopoly of the global market. Disciplines like archaeology see themselves inevitably questioned by emerging social movements that burst, in a truly visible way, onto the public order in the twenty-first century demanding changes in the political-economic agendas of the Nation Sates.

In this way, in current South American contexts, and emerging from a long-standing historical conflict, the disputes for land comprises of claims for the acknowledgement of ethnic difference for the returning of lands, the reestablishment of the subjects' and Indigenous peoples' rights over their cultural and natural heritage, and the defense against the indiscriminate advancement of exploitations with high ecological and social impact carried out on the part of foreign capitals with license from the States. These conflicts generate heated discussions of interest regarding the political, social, cultural, and economic importance of archaeological heritage in these scenarios, and over all, present new reflections around the possibilities of resistance and change that the communities possess in the conflicts facing the States and the new actors in the global market. All this is exacerbated in the Bicentenary of the South American Nation States, where they celebrate their colonial "independence." Now is the time to return to focus on the unavoidable topic of national heritage and calls

for the urgent revision of different agreements. This happens in the face of local trajectories marked by the violent silencing of cultural differences, absorbed by the homogenized projects of the modern republics. This is a critical moment and as such it is decisive to rethink the conservationist traditionalisms and strengthen the active social values that archaeological heritage has acquired in the long histories of pillaging and expropriation (Jofré 2010).

The collaboration between a discipline with a colonial history such as archaeology and the social movements of today must be submitted to necessary questions and revised in a global political scenario; in this course, it is strategically unviable to continue defending the autonomy of the communities in terms of the cultural relativism of conservationist intervention. The right to difference in these relativist terms has promoted the perception of a substantive, stable, and permanent cultural heritage. So in this form, culture and its heritage had to be perceived as the result of a historic process, the product of an accumulated historic experience captured like something stable through the concept of culture (Segato 2011).

Contrary to cultural relativism, the accompaniment of the social movements, and this is the challenge for a discipline like archaeology that is accustomed to intervening from a place of power and privilege, anticipates the acceptance of historical pluralism, the right to "*one's own history*." Each people plot their history passing, the inconsistency of their own cultural discourse, overcoming their contradictions, and above all choosing their alternatives, interacting within the heterogeneous index of the nation. Following Rita Segato (2011), this means accepting at least two principles: (a) that the collective subjects of this plurality of histories are the people, and they possess the deliberative autonomy to produce their own historic process; (b) that this collective subject, this living people, is not a stable cultural heritage with fixed and unchanging contents throughout time and space, rather it is the self-perception on the part of its members of a shared history that comes from a past and is directed toward a future.

It remains to be said that this accompaniment and collaborative experience between archaeology and social movements to achieve a successful association founded in common objects toward the decolonization is more and more compelled to find ways to reinforce and defend the autonomies of the people, therein lies the political and social predicament of the discipline in these times.

Introduction

Archaeologists reconstruct the activities and interactions of individuals using the accumulated material culture of the past, yet detecting these interactions can be difficult using traditional archaeological analytical tools. The development of a methodological framework emerging from graph theory, coupled with the growth of computational power and a growing multidisciplinary theoretical framework aimed at interpreting these analyses, have eased the difficulties of uncovering, analyzing, and interpreting networks in the past. From examining physical locations of sites and how they interact together (Peregrine 1991) to examining trade routes and migration pathways (Hofman et al. 2018), and the exchange of

ideas across time and space (Mills et al. 2013), network approaches have infiltrated archaeology and grown exponentially in published studies (Brughmans 2013; Mills 2017).

Definition

At its most basic, network analysis examines how entities connect to other entities. These entities, commonly called nodes, can represent any number of objects: cells in a body, people, species, households, and even cities have all been the subjects of network analysis. Archaeologists often examine artifacts, individuals, or archaeological sites as the nodes (the points of connection) in networks; nodes can have additional information attached to them that can be incorporated into the analysis and comparative scales of analysis can be used as well (Borck et al. 2015). For instance, if the nodes are archaeological sites, they can include information on size, estimated population, surrounding ecosystems, environmental context, artifacts, and/or public versus private architecture.

The connections among nodes are called edges, ties, or relationships and are a fundamental component for allowing measurements and analysis of the network as a whole. Common *social* network connections include relatedness, consumption practices, marriage, exchange/trade, and raiding. In an example of a trade network, Crabtree (2015) graphed exchange networks of goods between simulated households, creating the social networks explored in Fig. 1. While many connections will directly link two individuals, edges can be created from many different data types and do not necessarily have to incorporate direct interactions between two individuals. Alternatively, network analysis can allow researchers to explore ideational concepts like memory (Fig. 2) by exploring the relationship among curated material objects and their direction of manufacturing origin. Directionality within the relationships is often difficult to observe archaeologically (i.e., A → B, but not B → A) but is usually possible with many text-based and sourcing-based data. Other information can include the strength of the tie, for example, measuring how many times the connection occurs or the proportion of similarity within a multi-categorical assemblage.

The quantification of these links among nodes is what makes social network analysis so valuable to archaeological studies since it allows statistical analyses of how all of the parts interact with – and impact – each other. Put into a temporal sequence, this enables archaeologists to create robust predictions based on the underlying structure (or topology) of the networks, enabling researchers to advance interpretations of the past.

Archaeologists have long conducted visual analysis of networks. For instance, researchers interested in movement through architectural space have used the network-based space syntax approach, while anthropologically trained archaeologists are familiar with kinship diagrams (Fig. 3). In kinship diagrams, the nodes are individuals and the edges represent relatedness, and extra information can be coded into both the nodes and edges. For example, if the kinship network we are diagramming is a band of related foragers, we could look at the quantity of a resource each of them gathered in one foraging bout and then examine how much of these resources each of the individuals shared. We could then analyze the kinship diagram for who in the family was the most central for the redistribution of resources: who gathered the most, who gave the most, and who received the most?

Historical Background

While social network analysis has its theoretical roots in the early interests of foundational social scientists (e.g., Emile Durkheim's work examining relationships), the formal quantitative methodology was not really developed until the 1930s with the work of researchers like Jacob Moreno, William Lloyd Warner, Allison Davis, Burleigh Gardner, and Mary Gardner (Freeman 2004). Yet these early studies, while focusing on visual analyses of systematic relational data, did not develop computational tools to analyze the visual networks. In the 1940s, the step toward

Social Networks for Archaeological Research, Fig. 1 Social network representing exchanges of maize between year 760 and 780 in an agent-based model simulation of household exchange among Ancestral Pueblo people. In this network, it is clear that there are multiple groups that exchange within their groups but do not exchange to other groups, thus the large connected components toward the center and the multiple unconnected networks at the base of the graph. Colors correspond to generosity (red = more donations, yellow = only receiving). This network has 254 connected components, 918 nodes, and an average number of neighbors (exchange partners) of 1.612. (Adapted from Crabtree 2015, Fig. 14)

quantification was taken by Eliot Chapple, Conrad Arensberg, and Willard Quine when they created an algebraic model that calculated relative relationships among individuals not directly observed to be interacting (Freeman 2004).

From these beginnings, social network analysis burgeoned as a way to quantitatively analyze and computationally model social interactions. One of the most famous examples of these is Milgram's letter mailing experiment that gave rise to the popular concept of "Six Degrees of Separation." His studies dramatically revealed the small world nature of human society as well as how restrictive racial categories can be in limiting someone's access to people in other parts of society. These interests eventually merged with research on graph theory that had begun in the 1700s with Leonhard Euler's resolution of the Königsberg bridge problem from mathematics, also engendering the field of topology. Later, graph theoretical methods increased the exploratory and explanatory power of networks. By the 1980s and 1990s social scientists in fields outside of sociology also began incorporating network methods into their research more frequently.

Within archaeology, the 1970s were the birth of some of the first formal social network analyses, with works by Irwin, Irwin-Williams, Terrell, and White (Brughmans 2013). In the 1990s, social network analyses were pursued via the influx of personal computing with researchers analyzing the geographical distribution of

Social Networks for Archaeological Research, Fig. 2 Two-mode network of connections between archaeological sites in the Gallina region of the American Southwest and the directions from which curated ceramics were manufactured. Circles are archaeological settlements and squares are the direction of production of the foreign ceramics found at these settlements. (Modified from Borck 2018, Fig. 4.2)

Social Networks for Archaeological Research, Fig. 3 A kinship diagram showing culturally constructed relatedness. Triangles represent males, circles represent females. Here two types of ties are present: the equals sign represents marriage, while the solid line represents descent/sibling relationships

architecture within certain settlements, such as Cahokia, using formal centrality measures to argue for their primacy as central places in larger networks (Peregrine 1991). These measures, however, did not take into account all of the possible connections among nodes, only the most proximal. With increases in computing power the growth of archaeological network studies truly began (Brughmans 2013). Modern network analyses can be multi-scalar, an approach especially attractive for archaeologists who aim to understand individuals within communities, and communities within their greater landscape and cultural contexts. These methods, then, help link *data* to standing bodies of *theory* helping to formalize long-standing verbal models of human interaction in the past. Today, network methods are being integrated in diverse archaeological problems, both as the central hub of research (Mills et al. 2013; Giomi and Peeples 2019) and as baseline approaches that bolster hypotheses (Peeples and Haas 2013; Crabtree et al. 2017a). The rapid growth in the adaptation of network analysis in archaeology bespeaks both its utility in understanding the past and an increasingly computationally savvy profession. These approaches have already illuminated key debates and prove to provide greater insight as our methods improve, as more datasets are incorporated, and as more researchers pose more questions.

Key Issues/Current Debates

In archaeology, many of our central questions are inherently relational: e.g., how did power differentials between individuals influence societal-level decision-making (Bentley et al. 2005; Crabtree et al. 2017a)? Were people able to survive environmental disasters because of long-distance partnerships, and if so, who were they trading with (Borck et al. 2015; Fitzhugh et al. 2016)? How did people in pre-writing societies maintain connections across large spatial scales and times (Coward and Gamble 2008)? Many of these fundamental questions are difficult to resolve with traditional statistical and GIS based analyses of the cultural detritus we find in excavation and survey. Formal network models, however, can take aspects of the objects we find, categorize them, discover similarities, and use those similarities to explain cultural phenomena.

A key facet of network-based approaches and their popularity in archaeology is the ability to telescope between the macro- and micro-scales. Researchers can study not only the structure of the

overall network but also analyze the connections of individual nodes within the network. This is especially attractive for archaeology, where often we want to understand both regional patterns and localized phenomena. For example, in one of the most expansive social network initiatives in archaeology, Mills et al. (2013) have used similarities in the decoration of pottery to infer social networks. By categorizing well-dated and distinctly painted ceramics, they find clusters of similarity in ceramic assemblages across a large portion of the US Southwest and detect where and when networks become more globally interconnected or regionally isolated. These relational analyses highlight the social processes that underlie transitions in the American Southwest and bolster the idea that the small world phenomenon is not a product of modernity (Fig. 4).

Critiques

The two biggest critiques in archaeology's use of social network analysis are: ascribing sociality to objects, and minimal interpretation of results, often driven by application of the methodology without a clear understanding of how that methodology works.

Pots Are People v 2.0

Inferring social connections from artifact similarity and/or from the movement of objects is often a necessity for constructing networks due to the difficulty of observing the physical relationships or movements of people in the past. However, within archaeology, the critique of assigning agency to objects is deep and social network analysis has, to some extent, revived these debates. Does design similarity between two artifacts that

Social Networks for Archaeological Research, Fig. 4 Regional scale networks of ceramic similarity through time in the greater Arizona/New Mexico portion of the US Southwest. These maps summarize the strongest patterns of potential connectivity across the study area by displaying ties among all settlements with ≥75% of possible decorated ceramic assemblage similarity, color coded by the linear distance between settlements. Bar plots associated with each map show the relative proportions of connections of varying distance. The proportion of strong similarities among distant sites increases dramatically between the A.D. 1300–1350 and 1350–1400 intervals, in particular for areas south of the Mogollon Rim in central Arizona. This temporal plot shows that the spatial scale of connectivity among settlements dramatically increased over time. (From Mills et al. 2013, Fig. 2)

are hundreds of kilometers apart reveal a social network? Does this suggest trade routes? Or does this similarity reflect the serendipitous invention of similar styles miles apart? Or can it mean that someone in the past walked a long distance and accidentally dropped an object? Critics argue that equifinality and simultaneity mean that the construction of historic or archaeological networks based on things such as similarity of artifact design or similar proportions of decorated ceramic types is problematic at best or useless at worst. However, there are many ways that researchers have addressed these critiques. Below we briefly explore two of the most prominent methods.

First, researchers have compiled large datasets that enable a more nuanced and robust approach to studying the connections between artifact types and archaeological sites (e.g., Mills et al. 2013). Second, researchers have created agent-based models that incorporate networks, and then use those networks to compare against the archaeological record (Crabtree 2015).

Big Data – a current buzzword in both science and the media – has influenced archaeology, although the quantity of data archaeologists compile is relatively small-scale in comparison to that of other disciplines. Still, new comparative projects have compiled large quantities of data into compatible formats. As the amount of data increases, concerns stemming from sample size (e.g., whether networks simply indicate spurious patterns) often vanish. Additionally, large datasets can lessen concerns of anthropomorphizing data points, since researchers detect patterns in the aggregate instead of "chance" encounters. In other words, instead of suggesting that one pot moved from one area to another, finding similarities of design and structure in the aggregate bolsters interpretations of regions being connected through similar methodologies.

Pattern recognition in robust data assemblages often links archaeological network research with Complex Adaptive Systems (CAS) science. A complex adaptive system can be defined as being made up of multiple individuals who act and interact together, often in unpredictable ways that lead to changes in the overall structure that would not be predicted by individual behaviors. It is because of this definition that a CAS scientist often uses network analysis as one approach; the interactions between individuals lend shape to the network as a whole. A second approach used by CAS scientists is agent-based modeling, a method of creating simulations in silico that can examine how individuals interact together across space and through time. The combination of agent-based models and networks has proven fruitful for examining complex archaeological processes. For example, agent-based modeling approaches have shown that the generative processes for networks create distributions similar to those that we can detect in the archaeological record, helping to bolster confidence and understanding of network approaches (e.g., Graham and Weingart 2015). While critiques of agent-based models can undermine interpretations (e.g., oversimplification), the increasing refinement of, literacy of, and application of agent-based models ease these critiques, and as more researchers embrace these computational techniques, models will refine and understanding of them will increase.

Blackboxing and Data Interpretation

Another issue in network analysis in archaeology is the potential for misguided or missing data interpretation. While network analysis programs like Gephi, for example, compute multiple statistics based on principles in graph theory, interpretation of those statistics can be lacking. For example, scholars frequently report centrality scores for networks, barely moving past reporting these as being "important" nodes (Brughmans 2013). Moving beyond simply reporting statistics to interpretation can be achieved by focusing on the properties of the nodes (and the network) that lead to these statistics. For example, if the network was rearranged, what effects would that have for the flow of goods or information? Asking simple questions of the topology (what does it mean to be "central"?) can help practitioners move beyond just reporting statistics to uncovering powerful interpretations. Finally, as researchers use models as ways to directly test hypotheses, many of these critiques may well be alleviated, as direct hypothesis testing can lend a greater narrative power and help guide interpretations of results from "off the shelf" network packages.

Other fields have examined the implications of network topology of nodes leading to large gains in system understanding. In sociology, for example, network analyses have shown that weak ties can be just as important to the functioning of networks as strong, central, and highly connected nodes (Granovetter 1973). Comparing empirical and simulated networks generated from the same number of nodes and edges can lead to a more nuanced interpretation of network structure and help provide confidence intervals around the archaeological networks, lending to greater statistical significance of interpretations. In the energy sector, these simulations help predict power blackouts, while in ecology, examining importance of weak ties can have implications for extinction events (Crabtree et al. 2017b). These same approaches can be instrumental in archaeology, helping illuminate the processes that make certain sites important in a region-wide economic network (Peeples and Haas 2013).

International Perspectives

Several large projects have successfully used network analysis to explore social connections of societies across space and through time. The *Southwest Social Networks Project* catalogued similarities in ceramics and architecture to illuminate regional interaction networks that were affected by large-scale exogenous and endogenous events, such as migration, climate patterns, and warfare. This project compiled some of the largest archaeological databases to date, allowing for precise characterization of the various networks that bisected the greater US Southwest.

The large-scale ERC-synergy *Nexus1492* project, a collaborative project among Leiden University, the VU Amsterdam, and Konstanz University, examines Indigenous, African, and European interactions in the Caribbean using one of the deepest temporal databases that include pre-Colonial and Early Colonial sites. Because of the extremely violent nature of the colonial encounters in the region, both physically and culturally, descendant communities have often been disconnected from their pre-Colonial histories. *Nexus1492* is using archaeological data – such as ceramic style distributions and sourcing diverse material types – to rebuild this relational history as much as possible (Fig. 5). These archaeological histories are then being used in comparison to European histories to explore how the Indigenous world was represented, both accurately and inaccurately, within these texts.

The Kuril Biocomplexity Project, which involved Russian, American, and Japanese researchers, examined the 5000-year trajectory of human-environment interactions in the Kuril islands. Network analysis within this project illuminated deep-time risk mitigation networks for hunter-gatherer populations experiencing stochastic environmental events which led to vulnerabilities (Fitzhugh et al. 2016).

Finally, the French-based project *TransMonDyn* (Sanders 2017) studied 12 global transitions from the expansion of anatomically modern humans from Africa to the development of the modern rail system in France (Fig. 6), bringing together researchers in archaeology, computer science, geography, and history. While networks were not the central focus of this project, they provided a methodological approach to many of the studies to examine how the actions of people in the past led to expansions of populations, ideas, and industry, researchers are able to illuminate key drivers for societal change.

Each of these projects highlights the strength of network-based approaches. First, while network analysis is quite useful and revelatory on smaller datasets, these projects *analyze large amounts of data* allowing for greater synthetic understanding of the past. Generally, archaeological data is curated at the site-level, making comparison among sites and regions difficult. In the *Kuril Biocomplexity Project,* these datasets incorporating both cultural and ecological data enabled a more holistic understanding of the archaeology of the Kuril Islands. Compiling data from many sites together *enables cross-cultural comparison*, a key goal in many anthropological studies. The American Southwest, for example, is home to multiple different cultural traditions that are exemplified in both stylistic and technological ceramic attributes. The *Southwest Social*

Social Networks for Archaeological Research, Fig. 5 Sites from the Caribbean are represented as white nodes and grouped per landmass (green circles). Square sites belong to stylistic micro-area 1; triangular sites belong to stylistic micro-area 2. Grey nodes represent lithic sources and contemporary dates. Blue lines represent short-distance lines-of-sight; red lines represent key long-distance line-of-sight; grey lines represent presence of lithic artifacts at sites; black dashed lines represent sites' membership of stylistic micro-areas. (From Brughmans et al. 2017, Fig. 11)

Networks Project enables a comparison of these cultural traditions by compiling the large databases on pottery styles and tracking diffusion of designs and ideas across the southwest. These projects also *integrate quantitative and qualitative data.* For example, artifact sourcing information can be combined with textual documents and artistic media like the pottery designs discussed above. *TransMonDyn* effectively used both qualitative and quantitative data in their twelve cases, demonstrating the utility of using these to better describe the past. Finally, network-based approaches *incorporate multiple perspectives* allowing for a more holistic understanding of the past. *Nexus1492,* by incorporating African, European, and Indigenous voices into the study of Caribbean social networks, along with researchers from archaeology, geochemistry, genetics, heritage studies, anthropology, and computer science, explored the multiple ways that people interacted *in* the past as well as how contemporary communities connect *with* the past. This also demonstrates how social network analysis within archaeology can help balance the colonial-dominated historical record by increasing the amount of data from nondominant populations.

Other Network Approaches

While this entry has focused on social network analysis, there are many other approaches to using network science within archaeology. For example, trophic network analysis, or food webs, are showing a promising way to highlight

Social Networks for Archaeological Research, Fig. 6 Case studies from the TransMonDyn project. Network methods provided analytical techniques for several of their case studies

human/environment interaction in the past, and have already helped to shed light on the versatility and vulnerability of humans (Crabtree et al. 2017b). These studies have compiled large ecosystems of data and may provide a way to compare human/environment interaction worldwide, by analyzing the network structure as a whole as well as the properties of individual nodes (species or groups of taxa). Another network-like study is the study of least costs paths, which measure potential pathways across landscapes. Researchers have used these least cost paths to explore migration events in the past by looking at these migratory paths as edges, and intersections of these edges as nodes. Network analysis of cost-based travel corridors can be used to suggest which sites were important and why (Hofman et al. 2018).

Future Directions

We see several key points of direction for network analysis in archaeology. First, with the open data movement and digitally accessible data on repositories like tDAR, more datasets will be analyzed with social network approaches. Second, the development of methods to examine what natural variance of a network is will become more common place, allowing archaeologists to understand variability (as a proxy for statistical significance) in their own networks. Finally, more archaeologists

will adopt these methods into their own research, incorporating network methods into the digital archaeologist's toolkit in a similar manner that geographic information systems approaches were incorporated in the 1990s and 2000s.

One major roadblock in doing network analysis is the availability of data. Yet with increasing calls for data accessibility, including as a requirement for many granting agencies (e.g., NSF), these hurdles are being passed. With the availability of these types of data, more large-scale comparative projects can be completed. This will enable the growth of social network approaches to understand, for example, the connectedness of past populations across large geographic areas. We see the increasing availability of data as a positive development for networked approaches which will only enhance our understanding of the past.

However, even as more data becomes available, a challenge remains in the fragmentary archaeological record. We are left wondering if the data we have sampled corresponds to a real network, or if the amount of data we have gathered only forms a part of the actual network. Since networks are noisy and can be created with missing data, understanding variability to allow for a proxy for p-values will be instrumental in assessing how "real" our archaeological networks are. One approach, the exponential random graph model (or ERGM) may be useful for examining variability around observed archaeological networks.

Yet even descriptive statistics of networks (without examining variability around nodes) are impactful for understanding the past, and as archaeologists incorporate more and more digital tools into their research agendas, and as network analysis packages become more user friendly and ubiquitous, these tools are likely to become often-incorporated into archaeological analysis.

As computational power increases, and the use of large datasets that have unequal structure or resolution become easier and more common, network studies will undoubtedly shed further light on the archaeological past. These approaches may well herald new interdisciplinary collaborations and allow archaeologists to use these models of past social networks to understand our present and future.

Social Zooarchaeology

Nerissa Russell
Cornell University, Ithaca, NY, USA

Introduction

Zooarchaeology, the study of animal bones from archaeological sites, began with a straightforward concern with diet, later expanded to

include subsistence strategies. The post-processual turn in archaeology eventually filtered into zooarchaeology, bringing a concern with social and symbolic aspects of human-animal relations. This approach seeks to understand the full range of these relations in past societies. Although it has roots in earlier work, it has largely come into existence in the last 25 years, initially as very much a minority approach. Early concerns included feasting and meat sharing, as well as animal symbolism exhibited by structured deposition of taxa or body parts. At least some recognition of social and symbolic factors now inflects nearly all zooarchaeological work.

Definition

Social zooarchaeology is the manifestation of social archaeology within zooarchaeology, the study of animal bones from archaeological sites in order to learn about human behavior. Social zooarchaeology explores aspects of human-animal relations beyond the dietary and human-human relations negotiated through animals, including the value of animals as wealth and symbols, sacrifice and other ritual and religious roles of animals, taboo, and the overvaluation of meat and its use in transactions of status and relationships through meat sharing and feasting.

Key Issues/Current Debates/Future Directions/Examples

Given the rich variety of roles that animals and their products have played in human society, many topics fall within the purview of social zooarchaeology, although some have received more attention than others. Animals serve as key symbols in all societies, intriguingly similar to humans yet different from them. The most obvious evidence of prehistoric animal symbolism is their portrayal in art, from the Early Upper Paleolithic on. There has been a century of debate over the interpretation of hunter-gatherer rock art: is it hunting magic, information transfer about game animals, art for art's sake, or does it depict ritual, myth, trance visions, or animal deities? Zooarchaeology can contribute where there are associated animal bone assemblages and invariably shows that the frequency of species in the art does not match the frequency of those hunted (e.g., Altuna 1996), thus ruling out straightforward explanations of art as hunting magic or teaching aid. Not uncommonly, a florescence of hunting art and elaborate hunting equipment occurs at times when actual hunting contributes less than previously to the diet, suggesting a performative aspect of hunting related to (gender) identity rather than subsistence.

Zooarchaeology can also contribute to classic debates about taboos, where proscriptions on killing or eating certain animals mark social distinctions (gender, age, religion, ethnicity, reproductive status, etc.). While it is always difficult to argue from absence, ethnoarchaeological work has shown that traces of taboo animals do occur in the archaeological record, but they are restricted spatially and limited in body part selection (Politis and Saunders 2002). Thus careful attention to rare taxa may reveal the contours of animal taboos and indicate whether the taboo is total or applies only to a segment of the population. Hesse and Wapnish (1998) provide a sterling example of social zooarchaeology in their interdisciplinary treatment of the Israelite pig taboo. Drawing on textual analysis, anthropological ethnicity theory, and zooarchaeological evidence, they show that Israelite ethnic identity was originally based on ties to place, but these were disrupted by the exile in Babylon. Afterward, the pig taboo and other food proscriptions help to construct a more portable ethnic/religious identity.

Many ritual practices incorporate animals or animal parts. Burial rites are the best studied, with careful attention to placement, body part selection, and butchering and cooking traces helping to distinguish among funerary sacrifices, the remains of mortuary feasts and food provisions for the afterlife (e.g., Méniel 1992). Outside of funerary contexts, sacrifice has received little attention except where historical records attest it, but ethnography suggests it would have been common in most societies with

domestic animals. Zooarchaeology has the potential to resolve the question of whether all meat from livestock in classical Greece derived from temple sacrifices and hence the extent to which sacrificial demand shaped herding practices. Only very recently has classical archaeology started to explore this potential, with promising results (Ekroth and Wallensten 2013). An exemplary study (Isaakidou et al. 2002) of animal bone deposits and associated deposits of other items in the Mycenaean Palace of Nestor at Pylos not only establishes that burnt offerings already occurred in this period (a point of controversy based on textual evidence) but also reveals a previously unknown practice in which palace accountants recorded or archived vouchers of sacrifices/feasts (bones, weapons, and drinking cups) prior to the proper disposal of the bones in discrete pits.

Hunting is crucial to the survival of foragers, but a social perspective would argue that hunters might seek prestige as well as protein and calories. In addition to the evidence from rock art and artifacts discussed above, ethnoarchaeological and zooarchaeological studies of various times and places suggest that hunters often target large game even when smaller animals would provide more meat (e.g., Hildebrandt and McGuire 2002).

Domestication is a particularly intense human-animal relationship. A longstanding debate concerns how and why domestication occurred (intentionally or through the gradual development of mutualism) and indeed what it is (morphological changes in the body or appropriation as property). Thanks to advances in genetics and the work generated by the famous Russian fox farm experiments, we have a better understanding of the mechanics of domestication, with selection for tolerance for humans the key factor that sets in motion genetic, endocrine, and developmental changes in animals' bodies and behavior (Zeder 2012). This explains how a similar result can be obtained from the rather different paths various species take to domestication, as is increasingly apparent. Recently, social zooarchaeologists have shifted the focus from the exploitative to the caring aspect of human relations with domestic animals (e.g., Oma 2010).

Human-animal relations are not limited to hunting and herding, however. Pet keeping is widespread and both wild and domestic animals can be pets. Studies of the surprisingly common prehistoric human translocation of animals to islands reveal a complex array of relations. While some cases appear to be a matter of bringing domestic animals when settling islands and others are probably stocking islands with game, animals such as wild cats and foxes do not fit comfortably into either category and may have been brought so they would be available for ceremonial requirements. Cyprus has been particularly well studied in this regard (although the earliest phases of human occupation are still being clarified) and exhibits instances of all three of these categories as well as probable commensal hitchhikers such as mice and shrews (Vigne et al. 2011).

Domestic animals provide meat and sometimes also secondary products such as milk and wool, but they are also property and therefore can serve as wealth. At the least, animal property can be exchanged or gifted like inanimate items but with the additional feature that they can reproduce and thus increase the flock. Ethnographically, livestock are very often important stores of wealth and used to create and maintain human relationships through a wide variety of transactions. These include inheritance to perpetuate wealth, contributions to feasts, fines to resolve disputes, and most importantly bridewealth to transact marriages and affiliate the children to the father's lineage. Bridewealth requirements affect the demography of herds and need to be modeled along with productive strategies that maximize meat and milk or minimize risk when interpreting mortality profiles (the age and sex kill-off pattern produced by culling decisions). Animal wealth and particularly bridewealth are powerful inducements to adopt herding and to invest labor in raising as many animals as possible. This expansionary tendency may help explain the spread of agriculture through the Old World following the domestication of herd animals. Animal wealth is also particularly susceptible to raiding and may be associated with an increase in warfare. Most of the zooarchaeological work that explicitly

addresses wealth has been done in Southern Africa, where livestock arrived in the Iron Age and ethnography attests to the practice of bridewealth. Drawing on mortality profiles and other evidence such as dung accumulations, current evidence suggests that cattle became more important as wealth through time and that this process may have been regionally variable.

The recent ontological turn in anthropology, in which scholars acknowledge the existence and validity of different understandings of how the world works, has inspired some zooarchaeologists to approach ancient animals differently. Some seek evidence that past cultures treated (some) animals as persons (Hill 2013). Usually these are wild animals; as well as transforming animals into property, domestication also tends to remove their souls. A related application of ontological theory draws on Descola's (2013) classification of ontologies (totemism, animism, analogism, naturalism) based on perceived continuities between human and animal bodies and souls, seeking to identify these ontologies in ancient societies through their treatment of animal remains and representations of animals.

Meat is an excellent food, a compact source of protein, fat, and vitamins. However, people seem universally to value meat beyond its nutritional contribution. The act of incorporating other creatures into our bodies is fraught with guilt and symbolism: meat makes special meals. In particular, meat is often the focus of sharing, especially when derived from wild game. Hunters are usually obligated to share large prey, at least, beyond their immediate family, according to rules that vary among societies. There has been considerable debate concerning whether meat sharing is a kind of delayed reciprocity, a risk-reducing strategy, a way to gain prestige (and mates), meant to benefit relatives beyond the nuclear family (differentially directed at kin), or a means of building and maintaining social relationships. Evidence suggests that all these functions may occur in different places, sometimes in combination. Archaeologically it is possible to detect the circulation of meat through careful contextual analysis, especially at sites that were occupied for relatively short lengths of time, so with higher resolution. Depending on the rules, sharing may produce skewed body part distributions. Refitting or conjoining studies that match articulating bones or right and left sides from the same animal can also reveal sharing. In some circumstances zooarchaeologists can determine not only whether sharing occurred but also whether it was symmetrical or uneven, which helps to sort out the models outlined above (Enloe 2003).

Feasting is another kind of sharing, with the meat distributed after cooking instead of before. The social dynamics are somewhat different, however, with a generous host gaining prestige from a well-executed feast, while hunters are usually enjoined to modesty about their kills. Feasting has received considerable attention in archaeology in the last 25 years, largely thanks to the work of Dietler and Hayden (2001) that assigns it an important place in transforming human societies and creating inequality. The performative aspect of feasts makes them relatively easy to detect archaeologically. Large or fancy serving vessels may mark a feast, for example. Meat (along with alcohol) is often the centerpiece of feasts, so large concentrations of animal bones, often less processed and cooked in larger pieces or unusual ways, can signal feasting remains. Both because the large amount of waste is more problematic and because it may carry ritual power (feasts often forming part of ceremonies), the bones may also receive different or more formal disposal treatment. Recently, some have argued that there has been too much focus on feasting and too great a dichotomy drawn between feasts and ordinary meals. Rather, all meals carry symbolism and varying degrees of ritualization, and there is usually a range of scale and formality (Hamilakis 2008).

While social zooarchaeology tends to be associated with interpretive approaches typical of post-processual archaeology, in fact it is not limited to a single theoretical school. Adherents of human behavioral ecology are increasingly including social factors in their models, often characterized as costly signaling (performance of behaviors that demonstrate the superior fitness of the signaler by

showing they can afford to put themselves at risk). Zooarchaeologists are recognizing that the social values of animals and meat are key to understanding past behaviors. For the most part, social zooarchaeology does not require new methods: mortality profiles, body part representation, and traces of butchering and cooking contain much social information. Most social questions do require a contextual approach, however, and frequently integration with other lines of evidence. The real key is to build models that take social values into account along with economic values.

Society for American Archaeology (SAA)

William D. Lipe
Department of Anthropology, Washington State University, Pullman, WA, USA

Introduction

The Society for American Archaeology (SAA), founded in 1934, is "an international organization dedicated to the research, interpretation, and protection of the archaeological heritage of the Americas." It has more than 7000 members, including professionals from academic, cultural heritage, and museum fields, students, and avocational archaeologists. The society hosts a large annual meeting and publishes three scholarly journals, as well as a members' magazine. Policy is set by officers and a board of directors elected by the members of the society, and a professional staff is employed at its office in Washington, DC. In a number of ways, the SAA plays a vital role in the establishment and practice of CHM in the Americas (In the USA, CHM is usually referred to as CRM (cultural resource management)).

Guidelines for Ethical Practice

Protection of archaeological sites from looting and destruction has been a concern of the SAA since its beginning. The first president, Arthur C. Parker, stated that one of the new organization's goals was "...the conservation of sources. The fact that anyone with a spade has had the right to excavate ancient sites and hawk relics as a commercial venture has had baneful results" (Parker 1935: 3). In 1961, "Four Principles for Archaeology" were adopted by the SAA membership. These set forth several broad guidelines for methods, ethics, and training and stated that "collecting practices which destroy data" were to be avoided and that "state and federal statutes regarding preservation of antiquities and permits for excavation must be scrupulously observed" (Champe et al. 1961: 137).

The SAA's current eight "Principles of Archaeological Ethics" http://www.saa.org/AbouttheSociety/PrinciplesofArchaeologicalEthics/tabid/203/Default.aspx were adopted in 1996; they place CHM concerns at the heart of archaeological ethics. Principle 1 – stewardship – gives archaeologists an active responsibility to work for long-term protection of the archaeological record and for using that record for the benefit of all people. The second principle – accountability – requires a commitment to consult and attempt to establish working relationships with descendants and other groups affected by archaeological work. Principle 4 urges archaeologists to engage in public outreach and education with the aim of improving the preservation, protection, and interpretation of the archaeological record. Implications for stewardship and public benefits are also described for the other principles, which have to do with commercialization, intellectual property, reporting, records, and training. Also see Lynott and Wylie (2000) for further discussion. In 2015, the SAA adopted a *Statement on Sexual Harassment and Violence* in the context of archaeological education and work environments and published an accompanying *Guide*.

CHM Outreach and Educational Activities

Currently, the SAA has a number of programs, committees, and task forces that further its goals in CHM. The Education and Outreach Program produces and distributes materials that help archaeologists and educators bring information about archaeology and cultural heritage to students at all levels and to the general public. The "Archaeology for the Public" website http://www.saa.org/publicftp/PUBLIC/home/home.html serves as a clearinghouse for a large variety of educational resources. The SAA Public Education Committee provides leadership and advice to the board in this area, and committee members assist SAA staff on specific projects.

Separate committees are in charge of annual awards for excellence in public education and for outstanding efforts to enhance public understanding of archaeology. There is also a committee charged with encouraging improved coverage of

archaeology in the print and visual media; this committee oversees a Press Office at the annual meeting.

The SAA Government Affairs Program employs a full-time manager, who works with the SAA Board and both the Government Affairs and International Government Affairs Committees, to represent the archaeological community on governmental issues that have the potential to affect archaeological conservation and/or the practice of archaeology. Monthly bulletins regarding current governmental issues are circulated to members, and collaborations are pursued with colleagues and organizations in the broader historic preservation – CHM community. The SAA is one of the founding members of the advocacy group *Coalition for American Heritage*.

The SAA Committee on Native American Relations works to increase understanding by archaeologists about issues of concern to Native Americans and to promote better relationships between both groups. A Repatriation Committee deals with topics related to the repatriation of archaeological materials to descendant groups under US federal, state, and international laws. The SAA maintains an endowment to fund scholarships in archaeology or heritage management for Native American students, and the Native American Scholarships Committee is tasked with overseeing this program and selecting the scholarship recipients.

An active Online Seminar Series offers professional development opportunities for students and professionals. Members are also offered free online lectures given by prominent archaeologists. Many of the topics in both series are relevant to CHM practice.

Publications, Conferences, and Sponsorships

The SAA Annual Meeting regularly draws more than 3000 registrants, and the society sponsors the biennial La Conferencia Intercontinental de la SAA at a location in Latin America. The society publishes three peer-reviewed journals (*American Antiquity*, *Latin American Antiquity*, and *Advances in Archaeological Practice*), and the SAA Press publishes book length manuscripts. Its members' magazine – *The SAA Archaeological Record* – regularly publishes articles on topics broadly related to CHM. Articles in *Advances in Archaeological Practice* and books published by the *SAA Press* often deal with topics of special relevance to CHM.

The programs of both the Annual Meeting and of La Conferencia typically include forums and symposia that relate to the method, theory, and practice of CHM as well as governmental policies affecting cultural heritage. The conferences provide a venue for committee meetings, and at the Annual Meeting, US federal and state agencies often schedule staff meetings for their CRM specialists. The Annual Meeting features an award for Excellence in Cultural Resource Management, with the recipient designated by a committee assigned that task.

In the mid-1990s, the Society of Professional Archaeologists was transformed into the Register of Professional Archaeologists (RPA), under the sponsorship of SAA, the Society for Historical Archaeology, the Archaeological Institute of America, and the American Anthropological Association. The RPA recognizes professionals who have met basic educational and experience requirements and who agree to abide by the RPA Code of Ethics and Standards of Research Performance. Registrants also agree to take part in a formal grievance process if a credible complaint about their professional performance is filed with RPA. The SAA encourages its professional members to register, and a large percentage has done so. Although many RPAs are employed in academic settings, the majority work as consultants or managers in the CHM segment of the field.

Archaeological and Cultural Education Consultants, Takoma Park, MD, USA

Committee History

In 1991, in response to growing concerns about the state of the Society for American Archaeology's body of ethics, the SAA's Executive Board created a task force on ethics in archaeology, naming Mark Lynott and Alison Wylie as its cochairs. In November 1993, with funding from the National Science Foundation and the National Park Service, Lynott and Wylie convened a 3-day workshop in Reno, Nevada, attended by diverse members of the Society and nonmember individuals to discuss the then-current state of ethics in archaeology. The workshop participants crafted six draft principles of archaeological ethics. Since these were considered "draft" principles, they were presented to the SAA membership in various methods and comments solicited: in position papers at the April 1994 meeting of the SAA in Anaheim, California, as a Special Report of the SAA (with comments from non-workshop attendees) in 1995 (Lynott and Wylie 1995), in numerous presentations at regional archaeological or anthropological conferences, in the SAA *Bulletin*, in two discussion sessions held by Lynott at the 1996 meeting in Milwaukee, and in an *American Antiquity* article by Lynott (1997). After the adoption of the Principles of Archaeological Ethics by the SAA's Board of Directors in April 1996, a second, revised version of the SAA Special Report (Lynott and Wylie 2000) was produced to increase the educational utility of the process and to encourage discussion of ethical issues in the practice of archaeology. Since the initial formulations, three more principles have been added, bringing the total of principles to nine, providing a strong basis for continuing development of a stronger archaeological ethics program.

The Committee on Ethics became a standing committee of the Society in 1997, charged by the SAA's Board of Directors with promoting discussion and education about ethical issues in archaeology and proposing revisions, as necessary, of the Principles of Archaeological Ethics. The committee is not charged with enforcement powers or responsibilities and therefore does not enforce, oversee, or examine claims of ethical misconduct.

Major Impact

Education Programs

The Committee on Ethics maintains an active web presence as a means of fulfilling its educational mission. Its website offers resources for students on codes of ethics promulgated by other archaeological and anthropological organizations, as well as information regarding ethics as a general field of philosophy. In addition to these general resources, the Committee offers another program aimed at including student involvement with the concepts inherent in the ethical practice of archaeology.

One of the primary programs of the Committee on Ethics' educational outreach has been the Ethics Bowl, modeled on a similar program developed by the Association for Practical and Professional Ethics in 1995. The Society's first Ethics Bowl was held at the 2004 annual meeting in Montreal, Canada, and it has been included in the Society's annual meeting since then. Ethics Bowl organizers compile hypothetical cases that describe archaeological dilemmas that are used to initiate discussion about archaeological ethics and situations. Teams of college students use a debate-style competition to explore the ethics of archaeological practice. The competition is based on the abilities of the student teams to effectively communicate their arguments, to tie the ethical dilemmas to the legal and social frameworks which influence the discipline, and to analyze the impact of those issues on the discipline as well as non-archaeological stakeholders. The Committee also encourages the use of the Ethics

Bowl cases in classes relating to ethics in archaeology and anthropology.

The Principles of Archaeological Ethics has become a foundation upon which archaeological ethics has rested. But, while they have been viewed as a semipermanent document, their original authors viewed them as living documents subject to change as need arose. Therefore, the Society is open to revisiting and revising the Principles of Archaeological Ethics as the need arises. For example, the idea of "open access" brings with it the question of which data should be available and to what extent and how the availability of such data might contribute to looting and handling conflicting legal restrictions on posting and access. In such issues, the Committee does not represent only the interests of its US constituents but rather the interests of global constituencies, thereby making the revision of the SAA principles very important and more complex than simply applying US standards based on US stakeholders. Thus, the Committee on Ethics will continue to maintain an active role as a provider of resources and educational material relating to ethical practice in contemporary global archaeology.

Society for Archaeological Sciences (SAS)

Robert Sternberg
Department of Earth and Environment,
Franklin & Marshall College, Lancaster, PA, USA

Basic Information

The Society for Archaeological Sciences (SAS) is a professional society for those involved and interested in physical and natural science applications in archaeology and paleoanthropology. The purposes of the Society include establishing a forum from which current issues and advancements in archaeological science and archaeometry may be presented and discussed; promoting awareness and providing information for archaeologists, anthropologists, and other professionals about the potential and the problems involved in the application of techniques from the physical and natural sciences to archaeological scientific research; and maintaining an active program for the promotion and implementation of interdisciplinary research in archaeology.

During the International Symposium on Archaeometry and Archaeological Prospection in 1977 at the University of Pennsylvania in Philadelphia, five members of the acting executive board met to lay the groundwork for the formal organization and development of the SAS. The first issue of the *Newsletter* of the Society for Archaeological Sciences was produced in the summer of 1977. The founding SAS Acting Executive Board consisted of Rainer Berger, Karl Butzer, James B. Griffin, P. Edgar Hare, Richard L. Hay, Vance Haynes, Robert Maddin, George Rapp, Jr., Max Saltzman, and R.E. Taylor.

The articles of incorporation for the Society for Archaeological Sciences were filed in 1979.

SAS had about 100 charter members. Membership cost $5 US per year. The first meeting was held on April 25, 1979, at the Society for American Archaeology (SAA) meeting in Vancouver. Annual business meetings of the SAS now alternate between being held at the

SAA and at the biennial International Symposium on Archaeometry (ISA). Membership for the past decade has hovered around 300, with over 40% from outside the USA. The basic membership rate is currently $25; the increase over the last 40 years is consistent with the quadrupling of the US Consumer Price Index.

The presidents of the Society have been (in chronological order): Karl Butzer, R.E. Taylor, Jonathan Ericson, John Weymouth, George Rapp, Jr., Rainer Berger, Joseph Michels, Joseph Lambert, Jeffrey Dean, Garman Harbottle, Doug Price, Suzanne DeAtley, James Burton, Erv Garrison, Pat Martin, Rob Sternberg, Chris Prior, Arleyn Simon, Greg Hodgins, Aaron Shugar, Thilo Rehren, Sandra L. López Varela, Patrick Degryse, Rob Tykot, Marc Walton, and currently Rachel Popelka-Filcoff. The current president-elect (to become president in 2019) is Marcos Martinón-Torres. Thus, five of the past seven presidents have been from outside of the USA.

The office of the General Secretary was established in 1981, with R.E. Taylor assuming the post. All business affairs, including the maintenance of the membership files, membership renewals, elections of officers, and archiving of legal records, are organized by the General Secretary. R.E. Taylor held this position for more than 20 years until it was taken over by Rob Sternberg in the summer of 2002. Kyle Freund became the third General Secretary of SAS in 2017. The Society can be contacted through the General Secretary or other officers, listed on the SAS web page.

Major Impact

The official organ of the SAS has been its *Newsletter*, becoming the *Bulletin* with volume 12. The current annual volume number is 40. These publications have generally been issued on a quarterly basis. Some other milestones: the first stapled issue was volume 7. Bitnet email addresses first appeared in volume 10, with more than half of the officers and editorial staff showing email addresses by volume 12. Those who have served as editors of the *Newsletter/Bulletin* are (in chronological order): R. E. Taylor; Suzanne De Atley, George Rapp, Jr., Pat Martin, Rob Sternberg, Chris Nagle, Rob Tykot, Christian Wells, James Vanderveen, Vanessa Muros, and currently Thomas Fenn.

Members of SAS are also eligible for discount subscription rates to several significant journals of archaeological science.

Plenum Press and then Kluwer Publishers, now Springer, in cooperation with the SAS, published five volumes in the book series *Advances in Archaeological And Museum Science*: Mulholland and Rapp (1992), Taylor and Aitken (1997), Shackley (1998), Williamson and Nickens (2000), and Ambrose and Katzenberg (2001). The editorial board for this series has included Martin J. Aitken, Edward V. Sayre, R.E. Taylor, and Robert H. Tykot.

The SAS has sponsored archaeological science sessions at the SAA meeting since 1982. The R.E. Taylor Poster Award competition was established in 1998 to reward outstanding student posters presented at the SAA and ISA meetings. The SAS Student Research International Travel Award was started in 2012.

James Burton initiated the Internet activities of SAS, starting with the electronic bulletin board ArchSci in 1991. This morphed into the listserv SAS-Net and the ftp site SAS-Depot later in 1991. The SAS web site went up in 1997, and can now be found at the domain name www.socarchsci.org; it has been designed and managed by Destiny Crider. The listserv and web site are still active. In addition, an SAS blog was started in early 2009 by Rob Sternberg, Rachel Popelka-Filcoff and Destiny Crider, and a wiki containing announcements related to archaeological science was also brought online in 2009 by Rob Sternberg. Marc Walton initiated a Twitter feed (SocArchSci @Archaeo_Science) in 2014. These social media are not currently active, but you can now find SAS on Facebook!

The logo for SAS (Fig. 1) will often be used to identify its activities, such as the sponsorship of

Society for Archaeological Sciences (SAS), Fig. 1 Logo for the Society for Archaeological Sciences

the upcoming Encyclopedia of Archaeological Sciences to be published by John Wiley & Sons.

Society for Historical Archaeology (SHA) (Cultural Heritage Management)

Douglas D. Scott
Social and Behavioral Sciences, Colorado Mesa University, Grand Junction, CO, USA

Basic Information and Major Impact

Historical archaeology is the archaeology of the modern world. The field is global in scope and deals with all groups of people, not simply those of European descent, although most historical archaeologists focus on the period after the fifteenth century.

The Society for Historical Archaeology (SHA) is an educational not-for-profit organization established to promote scholarly research and the dissemination of knowledge concerning historical archaeology and to exchange information in this field. It holds an annual conference to discuss problems of mutual interest relating to the study of historical archaeology and to have members and invited guests present topical papers, discuss new or shifting paradigms, and present results of recent research activities. The Society is very active in keeping informed of legislation, policy, rules, and regulations which effect cultural resources in the United States and worldwide. SHA has a long-standing relationship with the Advisory Council on Underwater Archaeology, which shares the society's annual conference in January.

SHA has its beginnings at a conference held in 1967 at Southern Methodist University in Dallas, Texas. The society almost immediately began publishing the journal *Historical Archaeology* which is currently a quarterly publication published by Springer. A newsletter followed in 1969 also published quarterly. Special publications have grown as have topical and specialty on-demand publications. The Society maintains a website – http://www.sha.org/ – which contains a variety of

information including names of officers, committee chairs, annual conference information, lists of publications, a member's area, a research resource area, a link to the Advisory Council on Underwater Archaeology's website, and other relevant information on historical archaeology.

SHA is governed by elected officers and a board of directors. The governing body is composed of a president, president-elect, secretary, treasurer, two publication editors, six directors, and the chair of the Advisory Council on Underwater Archaeology. The officers serve for a 3-year term. The SHA employs an executive director responsible for business office functions. The Society is funded by membership dues and other sources including donations, grants, and publication sales.

Today the Society for Historical Archaeology is the largest organization in the world dedicated to the archaeological study of the modern world and the third largest anthropological organization in the United States. Parallel organizations exist in Great Britain, the Society for Post-Medieval Archaeology, continental Europe, and Australasia, the Australasian Society for Historical Archaeology.

Society for Historical Archaeology (SHA) (Historical Archaeology)

Vergil E. Noble
Midwest Archeological Center, U.S. Department of National Park Service, Lincoln, NE, USA

Basic Information

The Society for Historical Archaeology (SHA) is a scholarly organization devoted to the investigation, interpretations, preservation, and management of archaeological sites associated whether directly or indirectly with a literate tradition. SHA's primary period of interest starts with the spread of European peoples into other parts of the world during the fifteenth century and continues to the present day, though its subject matter is not limited to European cultures.

SHA traces its origins to a Central States Meeting of the American Anthropological Association held at St. Louis in 1965. Several archaeologists investigating historic period sites met there informally and concluded that a new society should be established to promote historic sites archaeology as a distinct discipline. Edward B. Jelks hosted the founding meeting at Southern Methodist University, in Dallas, Texas, during the 1st week of January 1967. About 100 persons attended the "International Conference on Historic Archaeology," which had 17 formal presentations on the program.

A special committee, chaired by Jelks, met there to lay the groundwork for what would become SHA. In conjunction with the formal proceedings, several business meetings convened to discuss the committee's recommendations. Critical actions included votes for organization of the new society and the election of officers. Also set

in motion were the processes of writing a constitution and bylaws, publishing a new annual journal, and planning for the first actual SHA meeting at Williamsburg, Virginia, in 1968. John L. Cotter, then of the US National Park Service, was elected to serve as SHA's first president. Society membership that 1st year was slightly over 200, mostly American, but including 13 in Canada and 1 each in England, Mexico, Chile, and Australia.

For much of its history, SHA was governed by a board consisting of a president, president-elect, immediate past president, secretary-treasurer, editor, newsletter editor, six directors, and the chair of the Advisory Council on Underwater Archaeology (ACUA), an independently chartered organization whose mission is to advocate, promote, and provide advice on responsible stewardship of underwater cultural heritage. A 2006 amendment to the SHA Constitution and Bylaws increased the presidential term from 1 to 2 years, eliminated the board seat of immediate past president, and divided the position of secretary-treasurer. A more recently approved change replaced the appointed positions of editor and newsletter editor with an elected editor for research (either the journal editor or co-publications editor) and an elected editor for communications (either the newsletter editor or website editor), respectively.

To date, there have been 46 presidents of the SHA; 32 of those individuals are still living. The incumbent president at this writing, Mark Warner (University of Idaho), with be succeeded by the current president-elect, Barbara J. Heath (University of Tennessee), at the annual meeting in January of 2020.

Major Impact

Today, with over 1700 members, SHA has become the largest scholarly organization dedicated to understanding the modern world through excavation and study of material remains. It is also the third largest anthropological society in the United States. Although based in the United States, with most of its members living and working there, the society is now truly international in its constituency. Its geographical scope correspondingly has broadened from a focus on the New World to a global perspective.

SHA has a large contingent of underwater archaeologists and, through terms of a memorandum of agreement, maintains formal cooperative ties with the ACUA. This close relationship is reflected in the fact that, since 1987, SHA's annual meeting has been officially called the Conference on Historical and Underwater Archaeology. The long-standing alliance between the two organizations also figured in accreditation of both SHA and ACUA as nongovernmental organizations (NGOs) for consultation and collaboration in the 2001 UNESCO Convention on the Protection of the Underwater Cultural Heritage.

In addition to its quarterly journal, *Historical Archaeology*, SHA publishes a quarterly newsletter, occasional special publications, topical readers compiled from journal articles, technical briefs, and underwater proceedings. The society also holds agreements with several academic presses (e.g., the University Press of Florida, the University of Nebraska Press, and Springer Publishing) for the joint publications of books relating to the discipline. Other important activities include informing government policy makers and educating the general public about historical archaeology and cultural resource management. Much of its public outreach is accomplished through the official SHA website, http://www.sha.org/, which includes more detailed information about the society and discipline.

Society for Historical Archaeology (SHA) (Modern World Archaeology)

James Symonds[1,2] and Mark Warner[3]
[1]ACASA Archaeology, University of Amsterdam, Amsterdam, Netherlands
[2]Department of Archaeology, University of York, King's Manor, York, UK
[3]Department of Sociology and Anthropology, University of Idaho, Moscow, ID, USA

Basic Information

The Society for Historical Archaeology (SHA) promotes the study of the archaeology of the modern world (CE 1400 to present). It was founded in 1967 and has grown to become the largest international society of its kind, with a business office in the city of Rockville, Maryland. The majority of the SHA's members work in North America and focus on the archaeology of the post-Columbian New World; however, the society's geographical scope extends to the study of colonial encounters between indigenous peoples and Europeans in other continents, especially Africa and Asia. Over the years, the society has collaborated with the Society for Post-Medieval Archaeology in the UK and the Australasian Society for Historical Archaeology. It has also embraced underwater archaeology, in addition to terrestrial archaeology, and co-hosts a joint conference in January each year with the Advisory Council on Underwater Archaeology.

The development of the SHA mirrored the growth of professional archaeology in twentieth-century America and was closely tied to advances in legislation to protect historic sites and to the rise of cultural resource management in the late 1960s and 1970s. The origins and history of the SHA have been succinctly described by Richard Veit (http://www.sha.org/about/history.cfm). Veit identifies a number of key academic meetings which contributed to the establishment of the SHA. These included the 1958 meeting of the American Anthropological Association in Washington, DC, where a symposium was organized on the "Role of Archaeology in Historical Research" (Cotter 1993), and an "International Conference on Historical Archaeology" held at the Southern Methodist University of Dallas, Texas, in January 1967 (Schuyler 2001: 1177). The first meeting of the SHA took place in the heartland of colonial historic archaeology in the United States, in Williamsburg, Virginia, in 1968.

Major Impact

For the past 52 years, the SHA has published the quarterly peer-reviewed journal *Historical Archaeology* which publishes articles on research methods, theories, and findings from global historical archaeological. The society also publishes a *Technical Briefs in Historical Archaeology* series as well as specialist monographs. The SHA has played an important role in popularizing modern world historical archaeology and has actively worked to share the results of archaeological investigations with a wide range of educational and public interest groups, with almost one million people participating in some form of historical archaeology outreach in 2018. It has also worked tirelessly to lobby for the preservation of historic resources, including both tangible and intangible heritage assets, in political circles.

All members of the SHA and those who participate in SHA activities are asked to adhere to a 7-point ethical policy which serves to protect archaeological resources from needless destruction and highlights obligations to the archaeological record, colleagues, employers, and wider public audiences. Participants in the organization's annual meeting are also expected to adhere

to SHA's Sexual Harassment and Discrimination Policy. The SHA has also sought to raise professional standards and reward individual excellence by presenting a number of awards at annual meetings. The most prestigious of these awards is the J.C. Harrington Award, for lifetime achievement and scholarship, which was first awarded to Charles H. Fairbanks, in 1983.

Society for Industrial Archeology (SIA)

Patrick Martin
Department of Social Sciences, Michigan Technological University, Houghton, MI, USA

Basic Information

Probably the most important group focused on industrial heritage in North America is the Society for Industrial Archeology (SIA). Founded in 1971, this membership organization was created "to encourage the study, interpretation, and preservation of historically significant industrial sites, structures, artifacts, and technology." Inspired by the example of a similar group in the UK, the Association for Industrial Archaeology, and purposefully separate from the contemporary Society for Historical Archaeology, the founders included archaeologists, museum curators, government preservation officials, architects, engineers, planners and historians, academics, and avocational enthusiasts alike. While there has always been a small core of international members, the base remains within North America. The use of the term "archaeology" is based on the principal attention given to the physical evidence of industrialization, but not limited to the use of the traditional archaeological techniques. This terminology has been both a blessing and a curse; while it widens the scope and appeal of the enterprise beyond a focus on buildings and/or history, it also confuses some who respond to the term "archaeology" in its most narrow connotations referring to excavation and/or antiquity. Increasingly in North America, the term "industrial heritage" is used to refer to this area of interest and activism, consistent with practice in much of the remainder of the world, and recognizes the combination of attention to both the research enterprise and the preservation/management dimension of the field.

Major Impact

Throughout its history, the SIA has combined a scholarly approach to the study and understanding of industrial heritage with an enthusiast, preservationist ethic. As an organization that includes significant membership from both professional and avocational ranks, this dual focus is a major defining characteristic. SIA publishes a peer-reviewed journal, *IA*, along with a quarterly *SIA Newsletter*, and a website rich with information. SIA holds two meetings annually in shifting locations to feature a mix of scholarly presentations and highly popular tours of both historic industrial facilities and active production and infrastructure sites. SIA runs occasional international study tours, as well, to showcase exemplars of preservation practice and remarkable site survivals in other countries. In addition, SIA includes several affiliated local and regional SIA chapters that serve as a focus for regional activities and

preservation advocacy. The chapters hold seminars, conduct tours, publish newsletters and websites, and participate in campaigns to recognize the value of industrial heritage resources in their communities.

SIA is a community of like-minded individuals and groups that share an interest in the industrial heritage in its many forms. Increasingly the members communicate via electronic social media, though many traditionalists cling to the more familiar venues of print and direct personal interaction. Publications are shifting to online sources at the same time that ink is laid on paper. To learn more about the SIA, visit http://www.sia-web.org.

Society for Medieval Archaeology

Sally M. Foster[1] and Sarah J. Semple[2]
[1]Department of Archaeology, School of Geosciences, University of Aberdeen, Aberdeen, UK
[2]Department of Archaeology, Durham University, Durham, UK

Brief Definition of the Topic

The Society for Medieval Archaeology exists to further the study of the period from the fifth to the sixteenth century CE. It does so by publishing *Medieval Archaeology* (a journal of international standing dealing primarily with archaeological evidence), a monograph series, and by other means of communication such as its newsletter and website, holding regular meetings and arranging conferences.

Medieval archaeology did not exist as a discipline in its own right at the time of the establishment of the Society in 1957, at the initiative of J. G. Hurst and D. M. Wilson. From the outset, this energetic Society has played an active and critical role in establishing and shaping medieval archaeology in Britain and Ireland (a special focus) and beyond. This is reflected in the contents of *Medieval Archaeology*. From the beginning, the journal has been central to the work of the Society and in many senses can be taken as a barometer of the development of the academic discipline and the challenges and opportunities existing in working within an inherently interdisciplinary and fragmented domain, where medieval archaeology has arguably lacked the confidence to establish its "own discipline's ability to write distinctive narratives" (Gilchrist and Reynolds 2009: 5–6). That the subject has expanded and matured across Europe is, for example, reflected in the birth of French, German, and Italian equivalents that in varying degrees have modeled themselves on the Society and its publications: *Archéologie medieval*, *Zeitschrift für Archäologie* des *Mittelalters*, and *Archeologia Medievale*. The iterative relationship between the development of the subject and of the Society is discussed directly and indirectly in two Society-edited volumes, *25 Years of Medieval Archaeology* (Hinton 1983) and *Reflections: 50 Years of Medieval Archaeology, 1957–2007* (Gilchrist and Reynolds 2009); see also Gerrard (2007).

As part of its 50-year celebrations in 2007, the Society made volumes 1–50 of *Medieval Archaeology* available free online to everyone, and the newsletters are also accessible on its website. In 2015 *Medieval Archaeology* was acquired from Maney Publishing by the Routledge Taylor and Francis publishing group, and in 2016 the journal moved to two issues per year. All volumes from 1 to 62 are now available via Taylor and Francis online. Subscribing individual and institutional members receive the journal *Medieval*

Archaeology (in hard copy and electronically), and individual members also receive hard copies of the all-color newsletter.

Since 1966, the Society has produced over 37 monographs dealing with particular aspects of the archaeology of Britain and Ireland between CE 400 and 1600, ranging from excavation reports to thematic overviews. Many of these appeared in recent years under the editorship of Christopher Gerrard.

A new development is the inclusion of a postgraduate student on council to represent the interests of students in general and to help promote activities particularly beneficial to them, notably student conferences reflecting the full breadth of interests in the Middle Ages and careers advice days.

The Society's presidents reflect the interdisciplinary outlook of the Society: R. L. S. Bruce-Mitford (1957–1959), W. A. Pantin (1960–1962), J. N. L. Myres (1963–1965), Eleanora Carus-Wilson (1966–1968), C. A. Ralegh Radford (1969–1971), A. J. Taylor (1972–1974), D. B. Harden (1975–1977), C. E. Blunt (1978–1980), J. G. Hurst (1981–1983), H. R. Loyn (1984–1986), A. C. Thomas (1987–1989), Helen Clarke (1990–1992), M. W. Thompson (1993–1995), M. Biddle (1996–1998), C. Dyer (1999–2001), R. A. Hall (2002–2004), Roberta L. Gilchrist (2005–2007), Leslie Webster (2008–2010), Mark Gardiner (2011–2013), Helena Hamerow (2013–2016), and Carenza Lewis (2017–2019).

Society of the Ship

Richard A. Gould
Department of Anthropology, Brown University, Providence, RI, USA

Introduction and Definition

The social order of ships occurs in both closed cultural systems that operate within the confines of the vessel at sea and open systems that interact simultaneously with the shore-based community that produces and supports them. The same can be said for shipwrecks as physical units of contemporaneity at the time of loss (so-called time capsules) versus the ways they are embedded in the context of ongoing natural and cultural processes that affect the postdepositional character of the archaeological record.

For our purposes, shipboard societies can be defined as floating communities that operate out of sight of land over variable distances and time. The ship itself can be small, like an ancient Polynesian voyaging canoe – a concept archaeologist Patrick V. Kirch called "the society of the canoe" in the 1980 PBS video production, *The Navigators* (Low 1980) – or it may be an ocean-going warship manned by hundreds of officers and sailors, such as the great eighteenth-century English line-of-battle ships described by historian N.A.M. Rodger in *The Wooden World* (1986).

S

Size is not necessarily important, but the circumstances under which the vessel and its crew operated are. Modern maritime behavior can provide useful comparisons with the archaeological record at shipwreck sites and serves as a source of testable hypotheses. The goal, however, is to find out "what happened" in the past to account for shipwreck remains that may belong to any culture, including non-Western ones, and to be prepared to recognize situations in the past that may have no modern counterpart.

Key Issues/Current Debates/Future Directions/Examples

One could hypothesize generally, for example, that the need for making decisions and acting on them quickly aboard ships at sea, especially under stress, requires a hierarchical social order and degrees of absolute authority not always found on land in the same society. Many historic examples exist of authoritarian conditions on ships, and these are sometimes encoded as regulations – in the case of naval vessels – or as contracts, in the case of merchant ships. Rodger's (1986: 210) account, however, notes a multitude of ways: "The peculiar nature of seafaring gave to ships at sea a natural cohesion unknown ashore, and perhaps permitted the Navy a legal code which. . .was remarkably lenient by the standards of its day." Rodger's account reveals the complexities of authority aboard eighteenth-century Royal Navy ships and in shore-based institutions like the Admiralty. He cautions against hypotheses that could oversimplify the nature of the social order at sea.

The archaeological record is not always specific enough to provide a detailed characterization of social life aboard ships at sea, but some important connections are at least possible and can be explored. Although isolated at sea, sometimes for long periods, shipboard societies are not hermetically sealed off from land-based institutions. Archaeology can often posit robust connections between land and sea in such cases. There are contemporary practices in maritime behavior that have become institutionalized and can serve as models for comparison when analyzing shipwrecks, especially in maritime commerce. For example, *flags of convenience, preference trading*, and *barratry* are established practices with the potential to produce recognizable archaeological signatures at shipwreck sites that characterize the conduct of maritime commerce in the context of Western, mercantile capitalism:

- *Flags of convenience* involve registering ships in nations which themselves do not have significant merchant fleets of their own, mainly as a way of evading safety rules, manning requirements, or other regulations by major maritime nations that can be costly, especially for shipowners operating on narrow profit margins.
- The *preference trade* is a protected form of commerce in which a nation requires that only ships that are registered in that country can operate legally between that nation's ports.
- *Barratry* is a term that covers various ways shipowners and/or captains intentionally wreck a ship for personal or corporate gain. Many of these wreckings are "insurance jobs," but this can also be good way to get rid of a ship that has become uneconomical or unprofitable to operate, especially when the cargo is more valuable than the ship.

All of these practices have evolved into social institutions in Western maritime commerce that can be hypothesized to produce recognizable patterns in the archaeology of shipwrecks. Flags of convenience and the preference trade, for example, both encourage shipowners to push their vessels one more voyage beyond their intended use lives – something that maritime archaeologist Larry Murphy (1983) refers to as the "one-more-voyage" hypothesis. This kind of behavior can produce shipwrecks that show extreme efforts at repairs to keep the ship in service. For example, large amounts of hardened mastic cement were found in the bilges of the nineteenth-century wooden cargo vessel labeled archaeologically as the "Barrel Wreck" at Loggerhead Reef in the Dry Tortugas, FL (Gould and Conlin 1999). This was a common expedient for ship operators of that

period to plug leaks and fill in rotting timbers to keep an otherwise worn-out ship in service. The location of shipwrecks in areas of high risk such as reefs and shoals or in locations dangerously exposed to bad weather and strong currents – termed "ship traps" – can also be a clue to this kind of behavior.

In more modern ships, the resale of supertankers and their continued use at sea under flags of convenience past their roughly 5-year designed use life reveals this same kind of risky behavior – often without regard for the safety of the crew or the environmental consequences of oil spills (Mostert 1974). It may be hard to distinguish to what degree flags of convenience or the preference trade accounts for these archaeological patterns, since they can both produce these effects, but such institutions are as much a part of the wrecking process as the proximate conditions of the vessel's loss.

The physical patterning that results from barratry can be harder to detect, since there may be efforts by the shipowners to conceal their activities. Forensic-like investigation of shipwrecks, however, can identify such behavior as the most parsimonious explanation for such patterning, as happened in the case of the iron barque *North Carolina*, wrecked in Bermuda on New Year's Day, 1880 (Gould 2005). Barratry and these other institutionalized behaviors are all products of mercantile capitalist commence in Western or Western-related cultures. But what about non-Western societies?

As the classic (1922) study by anthropologist Bronislaw Malinowski in the Trobriand Islands of the southwest Pacific showed, maritime commerce may operate in non-market-based economies involving movement and exchange of prestige goods between lifelong trading partners on different islands (termed *kula*). This kind of behavior cannot be explained with reference to Western models of market-based exchange, even though there is evidence that *kula* exchanges and voyaging included large amounts of goods in trade, as opposed to prestige (Gould 2011: 164–170). The canoes used by such voyagers are unlikely to produce identifiable wrecks, but this example and others like it make it clear that archaeologists cannot rely exclusively on Western models of maritime commerce for their hypotheses about ancient trade.

As maritime archaeologists explore shipwrecks of non-Western origin, they must be prepared to account for situations in the past that may have no modern counterparts, even in extant non-Western cultures. For example, how did our species make its way initially from Southeast Asia to Australia/New Guinea at least 40,000 years ago? Land-based evidence shows that this was the earliest known case of oceanic voyaging in human history, but no direct evidence in the form of boat or raft remains has been found archaeologically. Historic and modern watercraft produced by Australian Aborigines were lightly constructed and were poor candidates as models for this kind of voyaging. Similar issues concern the social groups that attempted such early voyaging. They were a colonizing population as well as the vessel's crew, so their size and composition need to be considered along with the implications for provisioning such voyages. We do not yet have the answers to these questions, and in such cases the present cannot serve as a direct guide to the past. It may be the differences rather than similarities to the contemporary society of the ship that will direct archaeologists to what really happened in the past.

Society of Vertebrate Paleontology of China (SVPC)

Ying Guan
Department of Paleoenvironmental Study, Institute of Vertebrate Palaeontology and Palaeoanthropology, Beijing, China

Basic Information

The Society of Vertebrate Paleontology of China (SVPC) is an international organization dedicated to the promotion of research and the protection of the paleontological and paleoanthropological remains of China. The society is affiliated with the Institute of Vertebrate Paleontology and Paleoanthropology of the Chinese Academy of Sciences. In October 27 of 1984, more than 150 paleontologists and paleoanthropologists, representing more than 70 institutions, gathered in Laiyang of Shandong Province, where the famous duck-billed dinosaur *Tsintaosaurus spinorhinus* was discovered, and held the inaugural conference of the SVPC. On that meeting, paleomammalogist Min-chen Chow was elected the president and paleoichthyologist Meemann Chang the deputy president. The secretariat office information is as followed:

Address

142 Xizhimenwai Street, Beijing, 100,044, China.
The official website: http://www.ivpp.cas.cn/jgsz/gkxh/gjzdwxh/
Tel: 86-10-68,351,363.
Fax: 86-10-68,337,001.
E-mail: bgs@ivpp.ac.cn

Major Impact

Vertebrate paleontological investigations and studies had been carried out for many years around China before the establishing of the SVPC, and the researchers are well represented throughout the country. There was an increasing need for an organization by vertebrate paleontologists and paleoanthropologists in China for many years. The founding of the SVPC has played this role well, and it has been dramatically promoting the study of vertebrate paleontology, paleoanthropology, and paleolithic archaeology in China and continually impacting these fields in the international academic field.

Since 1984, which was the year of naissance of SVPC, 15 annual meetings have been held in different cities in China. Currently, the SVPC comprises more than 300 members. The official language of the SVPC is Chinese and English. The biyearly meeting is held every 2 years, with participants mainly from China and some Asian countries but is now attracting more and more participants from the United States and Europe.

The date and location of these 15 annual meetings are as follows:

The first annual meeting: 1984 October 17–24, the city of Laiyang, Shandong Province.
The second annual meeting: 1987 February 22–27, the city of Suzhou, Jiangsu Province.
The third annual meeting: 1989 October 19–24, the city of Beijing.
The fourth annual meeting: 1992 August16–22, the city of Dalian, Liaoning Province.
The fifth annual meeting: 1994 November 24–December 1, the city of Chengdu and Zigong, Sichuan Province.
The sixth annual meeting: 1997 June 1–4, the city of Beijing.
The seventh annual meeting: 1999 April 25–30, the city of Yuxi, Yunnan Province.
The 8th annual meeting: 2001 November 2–6, the city of Shenzhen, Guangdong Province.

The 9th annual meeting: 2004 November 19–22, the city of Nanning, Guangxi Province.
The 10th annual meeting: 2006 November 20–22, the city of Sanming, Fujian Province.
The 11th annual meeting: 2008 September 20–23, the city of Taiyuan, Shanxi Province.
The 12th annual meeting: 2010 September 13–15, the city of Pingyi, Shandong Province.
The 13th annual meeting: 2012 August 25–27, the city of Erenhot, Inner Mongolia Autonomous Region.
The 14th annual meeting: 2014 April 19–21, the city of Qianxi, Guizhou Province.
The 15th annual meeting: 2016 August 21–25, the city of Daqing, Heilongjiang Province.

Soil Pollen Analyses in Environmental Archaeology

Rob Scaife
School of Geography, University of Southampton, Southampton, UK

Brief Definition of the Topic

Pollen liberated by flowers and spores from non-flowering plants contributes to the atmospheric pollen rain. After settling on the land surface, most is destroyed through oxidation and/or microbial and microfaunal activity. In fortuitous circumstances, pollen may be preserved in certain types of soil and can be extracted to provide data on past vegetation and environment. Pollen analysis is usually associated with lacustrine sediments and peat mires where the upward accumulation of sediments may provide a record of the changing vegetation and habitats at a local and more regional scale. Soil pollen analysis differs in that pollen and spores settling on suitable land where microbial decay is inhibited may be preserved through progressive incorporation into the developing soil profile. Such conditions occur where soils are of an acid character with no faunal (earthworm), mixing such as found on heathland, podzolic soils. In these circumstances, there is a general downward movement of pollen aided primarily by water flow, largely rain. Pollen and spores, however, do not move downward as individual grains but are locked in humic colloids. The downward movement is, therefore, slow and the breakdown and release from colloids depends on various pedological conditions. This results in a crude stratification of pollen within the soil profile with the oldest, irrespective of size, at the base of the profile. A soil pollen profile is, however, not truly stratified and while the youngest pollen is largely at the top and oldest lower down, at any particular level, there may be pollen of various ages (Dimbleby 1985). Longer residence in soils, the effects of bacterial action, and physical and chemical decay reduce the number of pollen grains present, resulting in differential preservation in favor of the most robust types. In Britain, this is often Lactucoideae (dandelion types) and fern spores. In acidic soils, with no faunal mixing, the highest absolute pollen numbers are in the upper levels, decreasing with depth. Thus, calculation of absolute pollen frequencies is an important tool in interpreting soil pollen data/assemblages coupled with knowledge of the differential preservation/resilience of various pollen types (Havinga 1964, 1985) in different soil and sediment types. Long-term study into taphonomic processes has been carried out to aid interpretation of palaeo-pollen spectra (Jewell and Dimbleby 1966; Dimbleby in Evans and Limbrey 1974; Havinga 1985). Interpretation of such stratified soil pollen thus requires a different approach to that of peat and lacustrine sediments.

The only principal contradiction to this is in soils where there is a buildup of a surface humus horizon as in a podzolic heathland soil (Ah) and woodland mor humus. Here, there may be a

stratigraphical accretion of pollen upward as humus continues to accumulate. High biological activity and breakdown of plant cellulose is carried out by microorganisms and fungal activity. With the former, ingested pollen is excreted to form *copromor* and the latter, *mycomor* (Stockmarr 1975). Changes in woodland structure through human activity may result in a change of the type of mor humus and rate of accumulation (Iversen 1964; Aaby 1983). In such mor humus, pollen may be remarkably abundant.

Historical Background

Soil pollen studies have been widely used to correlate vegetation history with soil profiles and development (e.g., Iversen 1964; Vuorela 1982). Professor G.W. Dimbleby pioneered and carried out numerous soil pollen analyses throughout Britain especially relating to archaeological contexts (Dimbleby 1955, 1957, 1985). When applied to soils buried (palaeosols) and preserved under archaeological sites, burial mounds, banks and by colluvium or other sedimentation, the technique has proved exceptionally useful in providing records of the vegetation prior to burial and information which may be directly relevant to the site occupation. The decrease of pollen down the profile can also be used to identify the old land surfaces where they are not visible in the overall profile and also to identify turves which (often inverted) were used to make up a funerary mound.

Dimbleby (1962) demonstrated that depletion of brown earth soils developed under deciduous woodland on sandy substrates initially had no pollen preservation. With increasing human activity (woodland clearance and agriculture), they became progressively more acid, resulting in heathland podzolic soil and consequent pollen preservation. Such pollen profiles frequently show an initial phase of scrub woodland (often hazel) with occasional traces of the preexisting woodland which was replaced by heathland vegetation on true podzolic soils. While such (podzolic) acid soils are favored for soil pollen analysis, in some circumstances, useful data can be obtained from calcareous soils developed on limestone lithology. This has proven valuable in establishing the vegetation and environment of the substantial areas of the chalklands of southern England through the analysis of prehistoric, subbarrow soils in this region (Dimbleby and Evans 1974). In such soils, due to faunal (largely earthworm) mixing, pollen may be distributed evenly throughout the soil. Absolute pollen numbers are generally small, and the potential for differential preservation and overrepresentation of taxa which have a robust pollen wall (exine) is substantially greater.

Somaliland: Cultural Heritage Management

Sada Mire
School of Oriental and African Studies, University of London, London, UK

Introduction

The Somali peninsula has a rich heritage relevant to the world. Many ancient world civilizations have left their mark on this area, a connection facilitated by the region's strategic location, connecting Arabia, Africa, and Asia through the Red Sea Coast, the Indian Ocean and hinterland routes to North Africa, and the Swahili Coast. Ancient long-distance trade is confirmed by archaeological finds from Ras Hafun that demonstrate a Greco-Roman trade affiliation (Chittick 1975; Smith and Wright 1988). Furthermore, historical sources in Greek, *The Periplus of the Erythraean Sea* (translation Schoff 1995), and Chinese (Freeman-Grenville 1962) also verify long-distance trade, and Somali's own seafaring traditions in different prehistoric periods (Hourani 1995) attest to contacts with India, China, North Africa, Arabia, Persia, and Eastern Africa, with which Somalis share Swahili culture (Chittick 1969). Arabic (Gibb 1962) and Portuguese sources provide accounts of medieval coastal towns such as Muqdisho, Merka, Baraawe, Berbera, and Saylac. The commercial and cultural contact network in the hinterland is reflected both in archaeological remains (Smith and Wright 1988) and other sources such as oral tradition and historical records. Recent unpublished archaeological discoveries show links with ancient Egypt, Roman, and Greek world, South Arabia, India, and Ming and Yuan dynasty China. It is therefore clear that the region is a cultural crossroads.

Key Issues/Current Debates/Future Directions/Examples

In the last two decades, a man-made disaster has led to the destruction of an entire people's heritage. Somali cultural heritage property has become one of the irreplaceable victims of the longest recorded civil war in the world (Brandt and Mohamed 1996; see also Jama 1996; Abungu 2001). The commencement of the civil war triggered looting of the museums. The Garesa National Museum in Mogadishu and the Hargeisa Regional Museum have both long been emptied. Warlords commission systematic illicit digging of sites. Also the intangible heritage has recently been threatened by strict interpretations of Islam which prohibit the traditional performance arts, dances, songs, and dresses. Somali tangible and intangible heritage continues to suffer the ongoing civil war.

The failed state of Somalia is officially under the UN-backed Transitional Federal Government, but the country has in fact since 1991 been divided into at least three parts; the northwestern region is reclaiming independence in a quest for re-recognition of Somaliland (a country that existed for a week in 1960 when it gained independence from Britain and joined Italian Somalia voluntarily). Somaliland is now a de facto state

and enjoys peace and security. Puntland is semi-autonomous but is devastated by piracy, and South-Central Somalia is mostly controlled by Islamist groups.

In addition to the war, however, other factors have also contributed to the neglect of Somali tangible heritage both by Somalis and the international community (Mire 2007). One major issue is the approaches to cultural heritage before the war. Prior to the war, Somali tangible heritage was not managed properly. The Italian colonial administration set up the first sub-Saharan ethnographic museum in Somalia, but after the Italians left, this museum was allowed to deteriorate. The reason seems to be that Somalis did not understand the need for an ethnographic museum when most of the population was living still with the objects that the museum displayed. One of the former directors of this museum suggested that content was "backward" objects from the countryside, things that his grandparents were still using (Mire 2007). This is confirmed by Italian exhibition publications of the time, such as Caroselli (1934) and the exhibition catalogue *Museo della Garesa*. More recently, UNESCO tried to develop this museum by providing museum development experts (e.g., Posnansky 1979; Crespo-Toral 1988), but UNESCO's approach was not endorsed, and its recommendations were neglected by the Somali government. UNESCO failed to understand that the Garesa Museum was not a self-representation of the Somali people. It displayed objects from the nomadic lifestyle as the only identity of the Somali, and this approach was not popular in a time of struggle against colonial mentality and rule. Also the Somali dictatorship failed to ratify the 1972 UNESCO World Heritage Convention, and it did not draft any national heritage laws or policy. Heritage legislation was far from sufficient and in fact almost useless (see Jönsson 1983 for examples; Brandt and Mohamed 1996; Mire 2007). Also archaeological research material was taken out of the country with no reports (Jönsson 1983). Only a few people (Curle 1937; Chittick 1969; Brandt 1986, 1988, 1992) had attempted systematic archaeological survey before the current civil war. A few Somalis (External institutions that made effort to train local archaeologists were too few (see bibliography for references to the Swedish Aid Agency, the SAREC project 1982–1990 by Jönsson 1983; Broberg 1986, 1990, Broberg and Säfvestad 1988).) were involved with archaeological work (e.g., Jama 1996), but it seems all eventually ended up leaving the discipline altogether. All of this contributed to the lack of engagement of Somalis with the significance of their tangible heritage.

There was no infrastructure put in place for dealing with the notion of a museum and its local potential. Furthermore, archaeological research remained almost totally alien as very few locals were involved in it before the war. Hence, one of the reasons for the failure to preserve Somali tangible heritage over the few last decades is also due to the fact that Somalis do not associate archaeology with their heritage and identity. When studying Somalis' views on cultural heritage management and the significance of archaeological remains, it was noted Somalis have their own perceptions of heritage and methods of preservation. Somali have a knowledge-centered approach to heritage and its preservation (Mire 2007, 2008a, 2011). Understanding of this indigenous local approach to heritage and its preservation is paramount to any future and current involvement. Intangible and tangible heritage has been preserved through oral traditions and oral transmission of knowledge. Since there was no writing until 1973, Somalis have developed profound skills in transmission of knowledge and traditions through oral means. Somalis have strong intangible knowledge flowing from their experience in the landscapes in which they live. All aspects of life – cultural, social, and ritual – are maintained and developed through oral history, poetry, traditional performance art, and crafts production. Somalis regardless of where they reside (countryside, city, and diaspora) seem to keep their knowledge and skills acquired through experience as their heritage. To understand why Somalis do not preserve objects and monuments, it is important to understand their lifestyle. As nomads are always on the move, people carry very little, and instead it is vital to have the knowledge and skills to produce things when needed, to know the landscape and where to find raw

materials, and so on. Hence, preservation of objects is not important if one knows how to make these objects. This knowledge helped Somalis when they become refugees and fled their comfortable houses in the city and found themselves in the nomadic landscape. They were able to build portable organic huts and find water as well as use their ethnobotanical knowledge to treat illnesses. This holistic approach to heritage preservation as knowledge is key to Somali nomadic culture.

In post-conflict Somaliland (Mire 2008a, b), cultural heritage is key for development. The Knowledge-Centered Approach is used here to engage communities in heritage management (Mire 2011). Although archaeology is alien to them, through this Knowledge-Centered Approach, Somali communities have a role to play in the preservation of both their tangible and intangible heritage. However, the main obstacles in Somaliland are institutional capacity building and policy and strategy development. Since Somaliland is not a recognized state, it cannot sign or ratify the 1972 World Heritage Convention. Hence, heritage in Somaliland is suffering this lack of status. However, on a national level, cultural heritage is being put into the national agenda by the creation of the Department of Tourism and Archaeology which has a number of programs for implementation and development of heritage management strategies and for sustainable development. This involves, among other things, cultural resource management for sites, monuments, and development of museums.

The Local Education and Safeguarding Program (LESP) aims to assist communities and government staff to acquire basic knowledge of the significance, protection, and preservation of cultural heritage. The Department of Tourism and Archaeology has recruited local people in various areas, particularly to safeguard the most prominent archaeological sites. The program provides capacity building for the staff and communities based in different areas of Somaliland. The Knowledge-Centered Approach is critical here, because it assists in the acknowledgement that the locals possess knowledge about their heritage and can provide insights to its preservation. This empowers locals and after having established mutual interest in a particular site, the government appoints a local person as a custodian of the site. These local ideas are recorded and incorporated into the actual work taking place at the sites.

There is also the National Inventory List (NIL) program in which both tangible and intangible elements and history of the sites are recorded. Recent archaeological interest in Somaliland has produced important sites including the rock art sites of Laas Geel (Gutherz et al. 2003), Dhambalin, Haadh, and Jilib Rihin (Mire 2008b). However, except for conventional surveys of sites, the Knowledge-Centered Approach has facilitated the investigation of what the locals see as significant heritage. Many times there are sites and features in the landscape that the archaeologist does not recognize as something important, such as mountains, springs, or even trees. Such seemingly insignificant landscape features are often more significant to the locals than archaeological sites. When carrying out archaeological survey of selected areas of Somaliland provinces, local people are often involved in the initial creation of data about the sites.

The Department of Tourism and Archaeology runs public education and heritage awareness media programs. Since the Somali culture is basically oral culture, media such as radios, television, and recently the Internet play an important role in the awareness raising. Through TV programs, the department explained the problem of illicit diggings of archaeological sites and the archaeological excavation process to demonstrate the damage being done to archaeological context and how this impacts the results and history writing of the Somali past. Particular attention was given to the possible benefits of archaeological sites for local populations and measures that stakeholders (governments, communities, business people, etc.) need to take to safeguard cultural property. Photographs are used to show the Somali people the destruction inflicted on their heritage by fellow Somalis. Also, international media have recently been given a role to spread the information about Somali heritage and the work taking place in Somaliland. Awareness films featuring the

department's work have been televised by Somaliland National News as well as international news agencies such as National Geographic TV, CNN, and BBC.

The Department of Archaeology and Tourism invests in training of its staff in tourism management. Although infrastructure is poor in Somaliland, the department managed to profile sites near the main cities to become tourist sites. In particular, rock art sites provide a ready resource for income generation through tourist activities. Somaliland receives cultural and environmental tourism, although in small groups. Also the department has students in universities in the Horn of Africa who will be joining the department after completion of their studies. The Department of Tourism and Archaeology's strategy for protecting sites prone to looting is by engaging the elders of the villages in awareness programs. Such awareness programs have prompted the elders to take up their own search of stolen objects. One example of such local initiative is some stolen decorated stelae near the town of Burco that were returned by the locals on their way to Boosaaso to ship the material to the Gulf and sold on the black market.

However, since there are no museums currently in Somaliland, most objects are recorded and documented by the department, and local people are registered as the official custodians of the objects until there is an official museum. The lack of museums contributes to the disappearance of artifacts. Potential collection- and artifact-repatriation projects as well as archaeological-rescue projects are extremely challenged by this lack of storage and research space. The Hargeisa Museum building is awaiting development, although it has been utilized as a hospital since the war. Also in Sanaag region, there are a couple of cultural educational centers. The Department of Tourism and Archaeology has hired some of the local women artists and craftswomen for these educational centers. This enables the local people to engage with their heritage and transfer skills and knowledge to the younger generations. Also the women produce material culture which they can sell to generate their own income. Recently, Horn Heritage Organization, a nongovernmental organization, has been set up to promote awareness and preservation of Somali heritage.

South Africa: Heritage Management

Katherine Cash
Campus Honors Program at the University of Illinois at Urbana-Champaign, Urbana, IL, USA

Introduction

South Africa is the southernmost country in Africa. It covers 1,219,090 sq. km, with 2798 km of coastline (Central Intelligence Agency (CIA) 2010). South Africa possesses a dominantly semiarid climate, with a subtropical climate along its east coast (Central Intelligence Agency (CIA) 2010). South Africa has a population of 49 million, with four predominant ethnic groups: black African (79%), white (9.6%), coloreds (8.9%), and Indian/Asian (2.5%) (Central Intelligence Agency (CIA) 2010). South Africa has twelve official languages, with IsiZulu being the most widely spoken, followed by IsiXhosa and Afrikaans (Central Intelligence Agency (CIA) 2010).

South Africa was first "discovered" by Dutch traders in 1652 and was used as a stopover point for trade routes between the Netherlands and the Far East; it was during this time that Cape Town was founded (Central Intelligence Agency (CIA) 2010). The English took control of the Cape of Good Hope in 1806, causing many of the Dutch settlers (Boers) to move further north (Central Intelligence Agency (CIA) 2010). Discovery of gold and diamonds in 1867 and 1886 caused a greater influx of people and the increased

degradation of the native peoples (Central Intelligence Agency (CIA) 2010). The Boers resisted the further-reaching control of the English but were defeated in the Boer Wars in 1899–1902 (Central Intelligence Agency (CIA) 2010). The Boers, now the Afrikaners, and the English established a rule together in 1910 as the Union of South Africa (Central Intelligence Agency (CIA) 2010). In 1948, the National Party instituted apartheid, and soon thereafter, South Africa was declared a Republic (Central Intelligence Agency (CIA) 2010). The African National Congress (ANC) opposed apartheid. After global pressure and years of turmoil in the country, the in-power regime negotiated a peaceful transition to majority rule (Central Intelligence Agency (CIA) 2010). The first multiracial elections were held in 1994, officially ending the apartheid and beginning the ANC's rule (Central Intelligence Agency (CIA) 2010).

In the years since, South Africa has been struggling with issues created or exacerbated by apartheid, including housing and education inequalities, poverty and health-care issues, as well as ANC infighting (Central Intelligence Agency (CIA) 2010).

Key Issues

Heritage Management Infrastructure

Heritage Laws

South Africa has one law that governs all heritage management in the country: the National Heritage Resources Act (NHRA) of 1999. This document serves multiple purposes including establishing a system for the management of heritage resources; encouraging good governing of these resources and empowering society to take a role in this governing for future generations; laying out principles and norms for the management of all heritage resources; creating a system for identifying, assessing, and managing heritage resources; establishing the South African Heritage Resources Agency (SAHRA); controlling the export of heritage resources and the illegal import of culturally significant items; allowing provinces to play a role in managing heritage resources of certain types; and creating laws and allowances for local authorities to protect heritage resources (Republic of South Africa (RSA) 1999).

This law takes special care in defining heritage resources, using an entire section to list all possible forms of a heritage resource (Republic of South Africa (RSA) 1999: Section 3). Most simply, heritage resources refer to any place or object of cultural significance (Republic of South Africa (RSA) 1999: Section 2.xvi). This law also mentions multiple times that any type of heritage resource should not be tampered with in any way without prior approval from SAHRA (Republic of South Africa (RSA) 1999: Sections 28–37). This document identifies the responsibility of heritage management as belonging not only to the government but also to the common person, for the sake of future generation (Republic of South Africa (RSA) 1999: Section 5.1.b). Though it does not state this explicitly, this law also acknowledges the existence of and the need to involve all stakeholders; it declares that heritage should be managed so that it acknowledges the right of affected communities to be consulted and to participate in the management of pertinent heritage resources (Republic of South Africa (RSA) 1999: Section 5.4) and that all relevant cultural values and indigenous knowledge should be taken into account as well (Republic of South Africa (RSA) 1999: Section 5.7.a). NHRA also acknowledges the role that tourism plays in heritage management. This law states that heritage resources contribute to tourism and should be developed and presented for this purpose (as well as for the purposes of research and education) (Republic of South Africa (RSA) 1999: Section 5.5); it also states that the identification, assessment, and management of heritage resources should contribute to economic development (Republic of South Africa (RSA) 1999: Section 5.7.d).

Though this law encompasses many ideas that are crucial to good heritage management, it appears to fall short on some accounts. The document as a whole seems more concerned with the bureaucracy behind the heritage management, rather than the methods and needs of heritage management; it spends a great deal of time

describing what permissions are needed from owners and organizations, rather than explaining the government's stance on methods, techniques, and authenticity. It also does not provide enough guidelines for the extent to which all stakeholders should be involved.

Heritage Institutions: Public

The main heritage management institute in South Africa is the South African Heritage Resources Agency (SAHRA). This agency was established by the National Heritage Resources Act (NHRA) in 1999 and is the government agency that is charged with the protection and administration of South Africa's heritage (Association of Southern African Professional Archaeologists (ASAPA) 2010). This agency is based out of Cape Town and has a regional office in each province (Association of Southern African Professional Archaeologists (ASAPA) 2010). SAHRA is run by an interdisciplinary council appointed by the arts and culture minister for South Africa and the chief executive officer; this position is currently held by Lynette Sibongile Van Damme (Association of Southern African Professional Archaeologists (ASAPA) 2010).

As the governmental agency for heritage management, SAHRA has a variety of duties, which are laid out on the home page of their website: "to coordinate and monitor the identification of our national heritage; to set a norm and standards and maintain the management of heritage resources nationally; to encourage and facilitate the development of provincial structures; to control export and import of nationally significant heritage resources; to develop policy initiatives on the promotion and management of our heritage; to nurture an holistic celebration of our history; to set national policy for heritage resources management, i.e. formal protection, general protection and management; and to develop an integrated and interactive system for the management of the national heritage resources" (South African Heritage Resources Agency (SAHRA) 2010a: home page). SAHRA provides protection and management guidelines to all types of heritage resources in South Africa, including archaeological sites, paleontological sites, meteorites, wrecks, burial grounds, and graves (South African Heritage Resources Agency (SAHRA) 2010b). They also supervise the creation of registers that are used to identify heritage resources and the creation of heritage areas (South African Heritage Resources Agency (SAHRA) 2010b).

Other governmental agencies include smaller regional ones, like Amafa aKwaZulu-Natali, which handles heritage resource management in KwaZulu Natal (Association of Southern African Professional Archaeologists (ASAPA) 2010).

Heritage Institutions: Private

The private or nongovernmental organizations (NGOs) in South Africa cover a wide variety of concerns and goals, from the integration of Black heritage and business strategy to the management of heritage resources that are not considered as such by the government to providing free consulting for heritage management groups and NGOs.

One such NGO is the Cape Town Heritage Trust, a private-sector, nonprofit organization. This organization was established by Cape Town's city council to take care of historic buildings and streets in Cape Town (Cape Town Heritage Trust (CTHT) 2010). Their website describes their mission as the conservation of the architectural, cultural, and natural heritage of Cape Town and its environs for the benefit of the inhabitants of the city and of the nation at large (Cape Town Heritage Trust (CTHT) 2010). This NGO works with the city council and the owners of buildings to improve and preserve historic buildings and other pieces of cultural heritage (Cape Town Heritage Trust (CTHT) 2010).

Other heritage NGOs include Nzumbululo Heritage Solutions (www.hessa.co.za), the Africa Heritage Society (www.africaheritage.com), and a number of province- or town-specific organizations that deal with natural heritage.

Examples

Part 1: Heritage Sites

South Africa's first entry onto the World Heritage List was in 1999, with the listing of Robben Island, iSimangaliso Wetlands Park, and the

Fossil Hominid Sites of Sterkfontein, Swartkrans, Kromdraai, and Environs (UNESCO World Heritage Center 1999a, b, c). Since then, another five sites have been added to the World Heritage List, along with twelve sites on the Tentative List. At the present, none of these sites are marked by UNESCO as being "at risk."

Sites on the World Heritage List

Of the eight sites South Africa has on the World Heritage List, four are cultural sites, one is a mixed cultural/natural site, and the remaining three are natural sites. My focus is on the cultural sites. The sites are described in the order in which they were inscribed on the World Heritage List.

Fossil Hominid Sites of Sterkfontein, Swartkrans, Kromdraai, and Environs This site was listed in 1999. It encompasses a variety of sites in Gauteng, Limpopo, and the Northwest Province. These sites contain evidence of early hominids, including the Taung Skull site, where the skull of an *Australopithecus africanus* was found, as well as the Makapan Valley site, where there are archaeological traces of human evolution, such as specimens of early hominids, such as Paranthropus, dating to between 4.5 million and 2.5 million years ago, and traces of human occupation, specifically the domestication of fire dating back to between 1.8 million and 1 million years ago (UNESCO World Heritage Center 1999a).

These sites meet two of the World Heritage criteria for possessing Outstanding Universal Value. The first met criterion is Criterion (iii): the archaeological evidence found here is an exceptional testimony to an extinct species while shedding light on our origins (UNESCO World Heritage Center 1999a). The second criterion met is Criterion (vi): these sites provide a vast reservoir of scientific data that will aid in the study of ancient humans (UNESCO World Heritage Center 1999a).

Robben Island This site was listed in 1999. Robben Island is a small island off the coast near Cape Town that has been in use since the seventeenth century as a hospital for socially unacceptable groups such as the mentally and terminally ill, a prison for both criminal and political prisoners, and a military base during World War II (UNESCO World Heritage Center 1999c). The prison on Robben Island held a variety of notable figures, including Nelson Mandela, who was incarcerated there for 20 years (Robben Island Museum 2009). The prison was closed in 1996, and the island has been developed as a museum and nature conservation area since then (Robben Island Museum 2009).

Robben Island fulfills two of the criteria for possessing Outstanding Universal Value. Criterion (iii) is met by the testimony it provides for the history of South Africa (UNESCO World Heritage Center 1999c). It also fulfills Criterion (vi) because it symbolizes the triumph of freedom, democracy, and the human spirit (UNESCO World Heritage Center 1999c, 2010).

uKhahlamba/Drakensberg Park This is a mixed cultural/natural site that was listed in 2000. This park stretches across KwaZulu Natal and the Eastern Cape Province and is known for its impressive geography and geology, as well as the concentration of native and endangered species, both flora and fauna, that this area is home to (UNESCO World Heritage Center 2003b). This park also contains many caves and rock shelters that hold the largest group of rock paintings found south of the Sahara. These paintings reflect the life of the now extinct San people (UNESCO World Heritage Center 2003b). The paintings show many aspects of San life, including hunting, dancing, food gathering, fighting, and ritual scenes (UNESCO World Heritage Center 2003b).

The uKhahlamba/Drakensburg Park meets four of the criterion for possessing Outstanding Universal Value. It meets Criterion (i) for the rock paintings – they are representative of a masterpiece of human creativity – and it meets Criterion (iii) because these rock paintings were recognized as a unique or exceptional testimony to a vanished culture (UNESCO World Heritage Center 2003b, 2010). The other two criteria met are Criteria (vii) and (x) for natural World Heritage Sites (UNESCO World Heritage Center 2003b).

Mapungubwe Cultural Landscape This is a cultural site that was listed in 2003. This landscape in the Northern Province at the confluence of the Shashe and Limpopo rivers was once home to the largest kingdom in the sub-Saharan continent, reaching the height of its power between CE 900 and CE 1300, before it was abandoned in the fourteenth century because of a rapid change in climate (UNESCO World Heritage Center 2003a). This landscape contains the nearly untouched remains of the palace sites and the surrounding settlement and two earlier capital sites (UNESCO World Heritage Center 2003a).

This landscape meets four of the criteria for possessing Outstanding Universal Value. Mapungubwe fulfills Criterion (ii) because the site provides evidence for the exchange of values that created cultural and social changes in Southern Africa during the height of their power; in the same vein, it also fulfills Criterion (iv) because the period of Mapungubwe's height of power and the effect of the cultural and social changes were part of a significant stage in the subcontinent's history (UNESCO World Heritage Center 2003a, 2010). The archaeological evidence found in this area provides a surprisingly complete testimony of Mapungubwe's rise and fall, fulfilling Criterion (iii) (UNESCO World Heritage Center 2003a, 2010). Finally, this landscape fulfills Criterion (v) by showing the impact of climate change and Mapungubwe as a culture that was vulnerable to irreversible change (UNESCO World Heritage Center 2003a, 2010).

Richtersveld Cultural and Botanical Landscape This is a cultural site that was listed in 2007. This landscape in the Northern Cape Province is home to the seminomadic, pastoral Nama peoples. Their pattern of life has persisted for over two millennia and includes the building of portable rush-mat houses, the only area in which this is still done, and seasonal migrations to grazing grounds (UNESCO World Heritage Center 2007). This way of life reflects old traditions that were once widespread, but no longer are (UNESCO World Heritage Center 2007).

This cultural landscape meets two of the criteria for possessing Outstanding Universal Value. The Nama peoples' way of life demonstrates a way of life that, when it was still a widespread way of life, played a major role in the history of South Africa; by this explanation, Richtersveld fulfills Criterion (iv) (UNESCO World Heritage Center 2007, 2010). Additionally, Richtersveld fulfills Criterion (v) because this area is one of the few remaining places were transhumance pastoralism, or the seasonal movement of people with livestock, is still practiced; this is an example of a traditional human land use that is now vulnerable (UNESCO World Heritage Center 2007, 2010). das könnte 2007 sein.

Part 2: Sites on the Tentative List

South Africa currently has 12 sites on the Tentative List, many of which were added to the Tentative List in 2004 or 2009. Eight of these are proposed as cultural sites; four are proposed as natural sites (UNESCO World Heritage Center 2009a). The cultural sites are, again, listed in the order they were proposed.

- *Pleistocene Occupation Sites of Klasies River, Border Cave, Wonderwerk Cave, and Comparable Sites Relating to the Emergence of Modern Humans*

  This cultural heritage site was proposed in 1998 and fulfills Criteria (ii), (iii), (iv), (v), and (vi) (UNESCO World Heritage Center 1998).
- *Kimberley Mines and Associated Early Industry*

  This cultural heritage site was proposed in 2004 and fulfills Criteria (i), (ii), (iv), and (vi) (UNESCO World Heritage Center 2004a).
- *Pilgrim's Rest Reduction Works Industrial Heritage Site*

  This cultural heritage site was proposed in 2004 and fulfills Criteria (i), (ii), (iv), and (vi) (UNESCO World Heritage Center 2004b).
- *The !Xam Khomani Heartland*

  This cultural heritage site was proposed in 2004 and fulfills Criteria (iii), (iv), (v), and (vi) (UNESCO World Heritage Center 2004c).
- *Liberation Heritage Route*

  This cultural heritage site was proposed in 2009 and fulfills Criteria (ii), (iii), and (vi) (UNESCO World Heritage Center 2009b).

- *The Cape Arc of Meridian*
  This cultural heritage site was proposed in 2009 and fulfills Criteria (ii), (iv), and (vi) (UNESCO World Heritage Center 2009c).
- *The Cape Winelands Cultural Landscape*
  This cultural heritage site was proposed in 2009 and fulfills Criteria (ii), (iii), and (iv) (UNESCO World Heritage Center 2009d).
- *The Namaqualand Copper Mining Landscape*
  This cultural heritage site was proposed in 2009 and fulfills Criteria (ii), (iii), and (iv) (UNESCO World Heritage Center 2009e).

Discussion of Sites on the World Heritage List and Tentative List

The sites inscribed on the World Heritage List for South Africa are perhaps indicative of what the South African government sees as important in the country's history. The cultural sites on the list favor themes such as the birth of the human race, precolonial civilizations, and the celebration of South African independence. None of these sites acknowledges the role colonialism and Europe played in developing the country. Whether or not these influences were considered unwanted or useful, all parts of a country's history should be considered equally when heritage is created. The omission of the colonial history is also an omission of those who live in the country who are descendants of the Dutch and English colonizers.

However, as the Tentative List suggests, heritage management in South Africa is beginning to acknowledge their colonial period. The Cape Winelands Cultural Landscape, suggested in 2009, acknowledges the role that colonialism, England, and the Netherlands played in the development of the wine industry there, as well as in the vernacular architecture (UNESCO World Heritage Center 2009d). In addition to this, there are three other sites that have been added onto the Tentative List since 2004. Kimberley Mines and Associated Early Industry, Pilgrim's Rest Reduction Works Industrial Heritage Site, and the Namaqualand Copper Mining Landscape are industrial heritage sites and acknowledge the role that England and the Netherlands played in starting off the industrial revolution of South Africa (UNESCO World Heritage Center 2004a, b, 2009e).

The order in which sites were added to the World Heritage List is also interesting. The first three sites, the Fossil Hominid Sites, Robben Island, and iSimangaliso Wetlands Park, were all added in the same year. These sites reflect, perhaps, a desire to be recognized by the world as a capable country; these sites establish the importance of South Africa to the rest of the world as the "Cradle of Humanity," as a free, self-governed country and as being wealthy enough to pay attention to issues that are a luxury, such as environmental conservation (UNESCO World Heritage Center 1999a, b, c).

Current Debates

Heritage Management Problems

Overall Problems

The predominant issues in heritage management for South Africa are laid out neatly in Colette Scheermeyer's (2005) article "A Changing and Challenging Landscape: Heritage Resources Management in South Africa." The first issue is one of balancing differing views of the same event. People in South Africa have bad memories of the apartheid, but good memories of their neighborhoods, social interactions, and lives during this period of time. It is the responsibility of those who practice heritage management to take both views and represent them fairly, without interference from their personal views or judgments (Scheermeyer 2005). So, despite the desire to portray the apartheid as entirely bad, one has to acknowledge that the injustices of the apartheid did not penetrate every aspect of life.

The second issue is the balance between the tangible and intangible. One must ensure that the intangible cultural aspects of a site are maintained along with the tangible, but on the flipside, the integrity of the site cannot be sacrificed while promoting the intangible heritage (Scheermeyer 2005). This problem manifests itself in the desire of communities to continue using culturally significant sites for ritual purposes.

The third predominant issue focuses on stakeholders. This problem is one that faces every heritage resource around the world. A holistic and fair approach to managing these cannot be achieved unless all stakeholders are identified consulted and involved (Scheermeyer 2005).

Site-Specific Problems

There are few sites with glaring difficulties in the heritage management. The most pressing problem is facing Wonderwerk Cave, one of the sites on the Tentative List. This cave, and the rock paintings within, is currently being threatened by erosion and the possibility of the cave collapsing (UNESCO World Heritage Center 1998).

Future Directions

Heritage management in South Africa is, by no means, an easy task. The presentation of heritage is plagued by negative heritage, conflicting views, and unwanted stakeholders. Despite these problems and inner turmoil, the South African government has made a strong, honest attempt at the competent management of their heritage. Their heritage management law tries to fairly address many of the issues that arise in heritage management, such as stakeholder claims and heritage preservation, though it does this at the expense of in-depth instruction on conservation. The South African government agency for heritage management is set up in an effort to include as many relevant disciplines as possible in heritage management.

However, some would argue that the effort and funding that is being put into heritage management and the World Heritage Sites and nominations is misplaced, given the staggering poverty rate of the country (around 50%) and the prevalence of HIV/AIDS and other infectious diseases (Central Intelligence Agency (CIA) 2010).

South Africa: Maritime Archaeology

Jaco Boshoff
Research and Exhibitions, Iziko Museums of South Africa, Cape Town, South Africa

Introduction

South Africa has roughly a 3,000-km-long coastline scattered with an estimated 3,000 historically recorded shipwrecks dating from the sixteenth century right up to modern times. According to the South African Heritage Resources Agency database, the resource represents 38 different nationalities. Shipwrecks concentrated in "hot spots" like harbors or rough stretches of coastline mostly because the southern tip of Africa was the gateway to the east for the European colonial powers before the construction of the Suez Canal. This heritage is dominated by Portuguese, Dutch, and British shipwrecks. The Portuguese opened up the sea route from Europe to the east, the Dutch colonized the Cape in the seventeenth century, and the British prevailed over the Dutch in the early nineteenth century. Academic interest in historical shipwrecks is a twentieth-century phenomena as in the previous centuries the economic value of salvage was the foremost motive for investigating the remains of old ships.

Definition

Maritime archaeology, as a subdiscipline, has had a checkered existence in South Africa. Maritime archaeology arguably started in the late 1980s with the appointment of a maritime archaeologist at the University of Cape Town. There was however an awareness of the importance of the underwater cultural heritage from quite early on with sporadic archaeological interventions. As with most countries with a coastline and shipwrecks, the inevitable scourge of treasure hunting reared its head, and a large part of the history of maritime archaeology in South Africa has to do with how this dilemma was handled by heritage bodies in the country. This, of course, implies the development of legislative efforts to control the resource. Although important in understanding the development of maritime archaeology in South Africa, it is not the focus of this review, as it will be discussed elsewhere in this publication (see the entry "▶ South Africa: Maritime Legal Management" in this encyclopedia). This entry will rather look at the development of the subdiscipline at museums and universities, in particular at Iziko Museums, as well as describe some of the archaeological interventions mentioned above. The development of maritime archaeology will also be discussed in the context of a change in

the political climate prevalent in South Africa at various times.

Historical Background

The South African Museum as the oldest museum in sub-Saharan Africa did not play a major role in the early years of shipwreck exploration in South Africa. In 1956, however, the director of the SA Museum, Dr. A.W. Crompton, offered the museum's assistance to the legendary physical "culturalist," strong man, and treasure hunter Tromp van Diggelen in his bid to recover "treasure" from shipwrecks in Table Bay (SACHM D1/4). The museum was willing to help with the identification of the items recovered as well as provide display area. An article in the Cape Argus in July 1956 estimated a fortune of 30 million pounds to be found on shipwrecks in Table Bay. Fortunately, not much came from this endeavor.

The situation changed in the 1960s when the South African Cultural History Museum (SACHM) was formed in 1964 by the splitting of the "European" collections from the Natural History and Ethnography collections of the South African Museum. This overtly political move from the Nationalist government of the day would, in the formation of the New South Africa in the 1990s, have an important impact in the direction taken by maritime archaeology in the museum world as will be discussed later in this entry. As an institution with its focus on European and therefore colonial history, the SACHM's interest in shipwrecks became apparent early on. This could be ascribed to the increased access to the underwater world due to the availability of scuba gear and with the founding of underwater clubs. As an example, the Atlantic Underwater Club (formed in 1953 in Cape Town) became more interested in shipwrecks with the publication by the Johannesburg Public Library's chief librarian, R.F. Kennedy (1955), titled *Shipwrecks On and Off the Coasts of Southern Africa*. It is interesting to note that not much note was taken of the work done by George Bass in the 1960s possibly because shipwrecks were still equated as sources of treasure and interesting artifacts.

This is typified by the SACHM obtaining a Customs and Excise license for the salvage of shipwrecks in 1965. The director of the newly formed SACHM, Dr. G.A. Wacha, mentions that his predecessors in the South African Museum tried several times in the past to obtain a salvage license (SACHM D1/4). This unfortunate association with salvage created an image of the brave divers "rescuing" valuable artifacts from the clutches of the ocean. Still the museum was trying to gain more control of the shipwreck scene, especially with lucrative salvage attempts like that of the British East Indiaman Fame (1822) taking place at the time by members of the Atlantic Underwater Club in Table Bay. A large amount of gold and silver coins, silver spoons and forks, gold jewelry, watchcases, nails, and a broken ship's bell were salvaged from the Fame (Turner 1988). The divers did donate about 299 items to the fledgling museum, starting the SACHM's shipwreck collection.

In 1966, Dr. W. Schneewind, replacing G.A. Wacha as director of the SACHM, contacted the Western Province Underwater Union and the Atlantic Underwater Club in an attempt to salvage artifacts from the wreck of Dutch East India Company 1697 wreck of *Het huis te Crayenstein* under the museum's salvage license. The divers did remove several items from the wreck but gave the museum a trifle of what was actually taken out. In a letter to the chairman of the Atlantic Underwater Club, Dr. Schneewind asked for more "showy" (sic) objects to arouse the interest of the board of trustees and the government (SACHM D1/4).

Schneewind was aware of the lack of standards and in particular the lack of protection. He wrote to the secretary of Cultural Affairs in 1968 suggesting strict legislation modeled on the Swiss Civil Code and Danish Legislation (SACHM D1/4). He also realized that public support was lacking. In a letter to Miss M. Shaw, secretary of the South African Museums Association, he suggested the creation of a specific expedition to draw the attention of the public and the government. Not much came of this however.

The South African Museums Association (SAMA) did, however, enter the debate. In 1971 at their Western Cape branch meeting, SAMA voiced concern about the plundering of shipwrecks (SACHM D1/4). Several important recommendations were made:

Wrecks older than 100 years to become the property of the State.
Wrecks should be protected like other archaeological sites.
Permits should be made available through the National Monuments Council.

Some control measures were also suggested:

A special directive should be issued to the police to help control the pillaging of wrecks.
A social conscience should be cultivated with the public.
Funds to be made available to purchase equipment and employ personnel to investigate and recover material from wrecks in a systematic manner with the voluntary assistance of weekend divers.
Not to purchase wreck material from dealers.

Dr. Schneewind appointed as chair to the Western Cape branch of SAMA was to approach the Department of Customs and Excise with these suggestions. These suggestions were later on referred to the Department of Cultural Affairs.

A reply from the Committee of Enquiry into the Protection of Cultural Treasures, appointed by the Minister of National Education, came in 1972 enquiring as to the desirability of controlling the export of cultural treasures. In the case of shipwrecks, Dr. Schneewind suggested again the implementation of legislation similar to the Danish model that included some of the suggestions of the SAMA committee, like the protection of shipwrecks older than 100 years. The governments' efforts apparently stopped here for the time being. In a March 1977 (SACHM D1/4) letter, Professor E. Axelson, a prominent expert on Portuguese history in South Africa, wanted to know what happened to the above suggestions to the government as he was at that moment inundated with calls from the press concerning the looting of the wreck of the *Sacramento*. In his reply, Dr. Schneewind again stressed his awareness of the need for protective legislation for shipwrecks.

In 1977, the Natal Museum's archaeology department (focusing mainly on the South African Iron Age) became interested in early shipwrecks because survivor's accounts contained the earliest descriptions of the southeastern seaboard and its inhabitants. Consequently, they started a project attempting to identify and locate some of the early sixteenth-century Portuguese shipwreck sites. They located and tentatively identified two of these very scattered wreck sites that of the *Sao Joao* (1552) and the *Sao Bento* (1554), but unfortunately did not take the research much further than this (Auret and Maggs 1982; Maggs 1984).

Another development in the 1970s was the discovery of a shipwreck during the excavations for the foundations of the new Civic Centre in the Cape Town foreshore in 1970. The Cape Town foreshore was created by large land reclamation projects in the 1930s, and in the process, many shipwrecks were covered unknowingly. Fortunately, for posterity, a city of Cape Town engineer, R.A. Lightley, an avid ship model builder, immediately recognized the timbers being uncovered. He managed to obtain permission to study the remains and eventually tentatively identified it as the remains of the Dutch East India Company ship *Nieuw Rhoon* scuttled in 1776 (Lightley 1976). This project produced the first proper site plan of a shipwreck in Southern Africa as well as a heretofore unmatched technical study of ship construction in the subcontinent.

Mention should probably be made here of the efforts by Graham Bell-Cross (curator of a museum in Mossel Bay) in locating several early Portuguese shipwrecks often working with divers and homeowners finding remains of survivor's camps in development of their beach homes (Bell-Cross 1988) along the Eastern Cape seaboard. Although Bell-Cross approached the study systematically often with the help of leading historians and sometimes archaeologists,

the result did not go further than purely descriptive work of artifacts found and statements as to the identification of the various possible shipwreck sites.

Meanwhile, the exploitation of shipwrecks continued unabated with recoveries from the Dutch East India Company ship *Meresteyn* (1702) on the Cape West Coast (Marsden 1976) and more troubling the recovery of bronze and iron guns from the seventeenth-century Portuguese wrecks of the *Santissimo Sacramento* and *Nossa Senhore Da Atalaia do Pinheiro* with most of these guns from the famous Bocarro foundry in Macao being sold for scrap. Some of the better examples did, however, find their way to the Port Elizabeth Museum and was probably the reason for the appointment of a curator responsible for shipwreck material in 1980. The other consequence was the amendment of the Heritage Legislation of the day in the form of the National Monuments Act of 1969, which was amended in 1979 by giving the relevant minister the power to declare any wreck older than 80 years as a national monument (Gribble 2002).

Key Issues

In the 1980s, legislation was improved, the first in 1981 proclaiming wreck sites older than 100 years (Abrahams 1987). The National Monuments Council now issued permits only for wrecks that were scattered and without identifiable structure or stratification. Conditions were that accurate recording techniques of an archaeological standard should be applied and that 50% of the artifacts had to be lodged at a collaborating museum.

This attempt of regulating shipwreck exploitation was by no means the solution of the problem as it was difficult to enforce these regulations with almost no funding and a desperate lack of personnel. The treasure-hunting community reacted in naming themselves "salvers" and not treasure hunters.

Archaeologists started to voice their concerns about the exploitation of shipwrecks along the South African coastline possibly because of the changing legislation that brought the low standards and inability of museums to cope with the influx of permit applications to the fore. At the SACHM, the shipwreck collection came under archaeological control with the appointment of a historical archaeologist in 1981 (Abrahams 1987). The shipwreck collection, however, was more of an onerous duty than a promising field of research as the museum had to respond to requests from divers for letters of cooperation. These letters most often took the form of one-liners promising cooperation with no conditions attached other than that the stipulations of the National Monuments Act need to be followed. The result was a very imbalanced collection as the museum seldom received or asked for the 50% of recovered artifacts. In fact, of 144 permits issued since 1982, the museum had letters of cooperation for 42 shipwrecks with only 3,000 artifacts dating from the sixteenth to the nineteenth centuries (Boshoff 2006). No specialized conservation unit existed, and the museum was often reliant on the treasure hunters conserving the artifacts received.

The SACHM was however attempting to get the investigation of shipwrecks on a more professional footing as proved by the organizing of a "Symposium on Maritime Archaeology" with a combination of archaeologists, treasure hunters, historians, and heritage specialists as speakers in July 1984 (SACHM D1/4). This was in response to projects like the exploitation of the treasure wreck of the British East India Company wreck of the *Joanna* (1682) that produced numerous artifacts especially silver coins that was sold into the public on the open market and even in diving magazines (Turner 1988). In hindsight, it is almost as if there was a naiveté from museums and heritage bodies in attempting to control treasure hunting by trusting that the treasure hunters would do the "right" thing. The excuse often aired was the lack of funding and qualified personnel at institutions like museums and universities.

The formation of the South African Historical Wreck Society in the 1980s was meant to bridge the gap between the academic world and the euphemistically named salvers. They tried to initiate several projects unsuccessfully and

unfortunately seemed only to legitimize the activities of treasure hunters. They did however help promote the general shipwreck artifact amnesty declared by the National Monuments Council in 1986 (Abrahams 1987). The amnesty was an attempt from the NMC to start with a clean slate. The idea was that divers would declare any objects illegally removed from shipwrecks and would be exempt from prosecution. At the end of the amnesty, any items not declared would make the possessor liable for prosecution. The most useful outcome from the amnesty was the files with data on the collections in private hands that could now be used for comparison with what museums have in their possession. This resource was however never utilized until later when the author analyzed the collections (Table 1) of the SACHM in relation to the records in the amnesty (Boshoff 2006)

In 1983, the University of Cape Town initiated a project on the British East India Company ship *Arniston* (1815). Among the students was I.H. Gericke, a well-known treasure hunter. Under the supervision of Prof. A.B.. Smith Gericke and another student, J. Jobling started the first attempt at a scientific investigation of a shipwreck in South Africa (Jobling 1982). Unfortunately, the project was marred by the fact that it did have a profit motive even though it does seem that Gericke was keen to get archaeologists and treasure hunters working together. This collaboration would eventually lead into Gericke sponsoring the post for a maritime archaeologist in the form of the Dutch archaeologist, Bruno Werz, appointed in 1988 in a dual position at the University of Cape Town and the SACHM.

South Africa: Maritime Archaeology, Table 1 Comparison of total artifacts in museums collection with artifacts reported in amnesty

Shipwreck name	Amnesty artifacts	Museum artifacts
Athens 1865	206	3
De Visch 1740	215	0
Fame 1822	165	299
Het Huis te Crayenstein 1697	18	16
Maori 1909	334	5
Meresteyn 1702	287	30
Trafalgar 1839	194	40

The 1980s would end with the formation of the South African Maritime Museum as a satellite of the South African Cultural History Museum and the appointment of Bruno Werz as alluded to above. At the same time, the curator of the new Maritime Museum, Tom Graham, started an honors degree at the University of Cape Town. He was following up a previous 1984 workshop on the practice of seal hunting in the nineteenth and twentieth centuries on the subantarctic island Marion (annexed by the South African government in 1947), by doing an in-depth study of historical documentation and visiting the island to record the sites reported archaeologically (Graham 1989). Under very trying circumstances, Graham managed to do two small excavations and record some of the sites. Although he did not manage to return to the island and continue the project, mainly because of his increased responsibilities at the South African Maritime Museum, he did plant the seed for a future project developing another possible direction for maritime archaeology in South Africa. The focus, however, would remain on shipwrecks steered by Bruno Werz. As the first person appointed as a maritime archaeologist, Werz had a huge task in front of him. Whether the strategies he followed to establish maritime archaeology on a firmer footing was successful is a tale of the 1990s and still a matter of debate.

Werz shared a position at the SACHM and University of Cape Town. He was also consulting for the National Monuments Council. This arrangement however was problematic from the start. The institutions were constantly vying for the loyalty of the maritime archaeologist. This was because the ground rules for this shared arrangement were never properly established. It is pointless to speculate who was at fault and what part internal politics played. Maybe if an infrastructure of some kind had been established before the appointment of a maritime archaeologist, matters would have been different.

Werz however attempted to start with project-oriented research with the investigation of the Dutch East Indiaman, *Oosterland*, wrecked in

Table Bay in 1697 as part of his maritime archaeology Project Table Bay (Werz 1999). This wreck was discovered by three local divers who reported it to Werz. An agreement was drawn up between Werz and the treasure hunters regulating the conduct of the project (SACHM D1/4). One important condition was that the archaeologist would have an opportunity to study the artifacts before the division between the museum and the treasure hunters. Although under archaeological control to a measure and not overtly acknowledged, it was, however, still a treasure-hunting project. It seems as if the lessons learned from the Arniston in the 1980s were not properly heeded as in the mid-1990s the project spiraled into disagreement and effectively stopped.

Another important project started in 1991 was Operation Sea Eagle under the archaeological direction of Werz, but more importantly incorporating other bodies like the South African Navy providing the logistical support (Werz 1993). This project was to record all the shipwrecks around Robben Island and was quite successful in the end but ironic as the island was still a political prison at the time. Unfortunately, the divergent nature of Werz's appointment at the university and the museum and the various disagreements with museum management as to the parameters of his position resulted in the museum not renewing his contract. The museum however decided to continue with the post by appointing the author first on a contract basis and then later in 1992 on a permanent basis.

Werz continued his association with the University of Cape Town and during this period produced a number of honors students and two master's students. This continued up to 1999 when his association with the University of Cape Town came to an end. He did however also start a project on the wreck of the *Bato* (1806) in Simon's Bay in 1996 and started the South African Institute of Maritime Archaeology (SAIMA) in 1999. After a short stint as a consultant for Arqueonautas SA in Mozambique in 2000, Werz started to focus on the activities of SAIMA but had to change tack when the main benefactor unexpectedly died. In 2012 Werz established the African Institute for Marine and Underwater Research (AIMURE) with himself as CEO ostensibly to stimulate and support African marine, maritime, and underwater research. In 2015 Werz started looking for the wreck of the *Haarlem* (1647). This wreck is widely recognized as facilitating the genesis of the city of Cape Town (Werz et al. 2017).

Meanwhile at the SACHM, stricter controls were put in place for permit holders from 1992 onward. Instead of giving a one-line letter of cooperation, the museum now required a proposal with a clear research rationale. The screening of projects for substantive content saw a sharp decline in applications. With this strategy, the museum started moving away from cooperation with commercially motivated projects counter to the existing legislation and charted a new direction for the future. The museum also started a small conservation laboratory prompted by receiving a collection from the British East India Company ship *Colebrooke* (1778). A large part of this collection consisted of wine bottles with the content still intact and in dire need of stabilization.

In 1993, the National Monuments Council contracted Lynn Harris from the University of South Carolina to compile an electronic database of the shipwrecks around the South African coastline, combining several of the existing paper-based databases in existence at the time. Another major task Harris undertook was the introduction of the Nautical Archaeology Society (NAS) courses to South Africa (Boshoff 1998). With the assistance of the author, courses were run in most of the major coastal cities in South Africa and even one in Namibia. One of the outcomes of the NAS program was the investigation into the British East India Company ship *Brunswick* (1805) lead by the author. Most of the participants in this project were volunteers, and it was the first noncommercial underwater investigation into a shipwreck in South Africa.

Although Harris' position at the National Monuments Council was a contract position and she left after a year, the post was retained and T. Durden was appointed on a contract. In 1994, Boshoff, Durden, and Werz together with a group of businessmen formed the Save Our Shipwrecks

Trust to promote the running of the NAS courses as well as starting a shipwreck route along the Cape coastline. The trust was mostly successful with the continuation of the NAS courses but dissolved upon the death of one of the founding members (David Meaker) and with Durden leaving for greener pastures. When Durden left, J. Gribble was appointed on a permanent basis at the NMC. This would put the management of shipwrecks on a firmer footing and continue the partnership between the National Monuments Council and the South African Maritime Museum. In 1997, Boshoff and Gribble visited Australia to investigate the state of maritime archaeology in that country. They also investigated some of the premier maritime museums in Australia but, more than that, presented papers at the Australian Institute of Maritime Archaeology's annual conference. One of the outcomes of this visit was the invitation by the Queensland Museum to Boshoff and Gribble to join the 1999 field season on the wreck of the HMS *Pandora* on the Great Barrier Reef. This gave them the opportunity to gauge their skill levels on a first-class large-scale underwater project.

The year 1997 also saw the resumption of the Marion Island project when Boshoff was invited by the National Monuments Council to be the archaeologist. The focus was to complete the inventory of sites started by Graham in 1989. This was largely successful with the archaeological documentation of 13 sites as well as making recommendations for the future management of the sites (Boshoff et al. 1997). A second visit to Marion in 1999 saw the documentation of further three sites as well as the excavation of a small boat washed up on one of the beaches (Boshoff and Van Schalkwyk 1999). Due to changes in the heritage industry, this project would lie dormant till 2011 when the Antarctic Legacy Project invited the author to do a review of the state of heritage objects on the island. This led eventually to a National Research Foundation project into the wrecking of the Norwegian sealer *Solglimt* (1908) and the study of the survivor camp (Boshoff et al. 2015). The survivor camp study led to a master's degree by T. van Niekerk, the first nonwhite, female maritime archaeologist in sub-Saharan Africa (Van Niekerk 2016).

International Perspectives

In 1985, H.J. Deacon, head of the department of archaeology at the University of Stellenbosch, visited Australia on a fact-finding mission concerning maritime archaeology. He was especially interested in the Australian legislation and the agreement made with the Dutch government about Dutch East India Company ships on their coastline. Deacon started to get some of his students interested in maritime archaeology although this was difficult as the facilities at the University of Stellenbosch were not as conducive to marine sciences as at the University of Cape Town that had a Research Diving Unit training students in the scientific mysteries of the underwater world. The author, however, is a product of that program even though it was short-lived and inadequate.

The 1980s in South Africa was, however, politically quite a turbulent time as the struggle against the apartheid government went into overdrive. This was the worst possible timing as maritime archaeology was starting to get serious attention from universities in this period. In the archaeological world, the academic boycott was instigated against South Africa at the World Archaeological Congress (WAC) in 1986. This was in part brought on by a motion tabled at the 1983 meeting of the Southern African Association of Archaeologists that asked for the condemnation of apartheid and other forms of discrimination by the association. The motion was never put to a vote, and delegates from Mozambique and Zimbabwe resigned in protest (Shepherd 2002). In a sense, this was the end of innocence for archaeology in South Africa as the WAC of 1986 demonstrated that politics could not be separated from the practice of archaeology. This would have a serious influence on the development of maritime archaeology in South Africa.

This naiveté would however take some time to break down and would take a new government in 1994 with the first democratic elections in South Africa before change started to filter

through and archaeologists adapted to a new direction in archaeology. This "innocence" was still evident in 1988 at another shipwreck symposium organized by the National Monuments Council, the South African Cultural History Museum, and the South African Historical Wreck Society (SACHM D1/4). Speakers were a mix of treasure hunters and archaeologists. Unfortunately, it seemed as if the divers still regarded archaeology as a technique of approaching shipwrecks rather than a way of interpreting the past (Smith 1988). Archaeologists tried to explain the rudiments of archaeology (Deacon 1988), but it still did not seem as if the treasure hunters took this to heart as no projects by the treasure hunters following on from the conference attempted to address the issues raised there. This conference was further evidence of the complete disregard of the political situation in the country at the time by archaeologists and treasure hunters. One could expect this of the latter as their main motivation was profit, but it seems in hindsight that the archaeological community involved with shipwrecks at the time could have at least attempted to address the future in this context as the writing was on the wall with the many riots taking place in South Africa. Maybe it was an indication of the standing of maritime archaeology in South Africa at the time as a fledgling subdiscipline eating away at the conscience of the mainly precolonial archaeology community with the overt focus on saving a cultural resource from the economic threat of treasure hunting.

In 1999, an important event occurred for South African archaeology as the World Archaeological Congress was held that year at the University of Cape Town. For maritime archaeology, it was the first World Archaeological Congress with a session devoted to maritime archaeology. Although small and only taking place in 1 day, it would lay the foundation for the larger and more complex sessions on maritime archaeology at the following World Archaeological Congress in Washington, DC, in 2003. Eventually under the leadership of Iziko Museums, the example of WAC would be a primer for the first maritime archaeology session at the Association of Southern African Professional Archaeologists conference in 2016.

Future Directions

From the first democratic elections in 1994, changes were on the horizon for the heritage industry. Frantic national meetings started in 1995 and many projects were put on hold. In the museum world, this would culminate in the formation of several large national institutions by amalgamating existing ones. In Cape Town, this resulted in the birth of Iziko Museums in 2000. This was a joining of the South African Museum, the South African National Gallery, the William Fehr Collection, and the South African Cultural History Museum. Of this group of museums, the South African Cultural History Museum completely lost its identity and was totally assimilated into the group. The young South African Maritime Museum became the Iziko Maritime Centre moving to much smaller premises after a losing battle with the property owner, the Victoria and Alfred Waterfront. For the next 3 years, the growing pains of the new institution caused a hiatus in new projects. For maritime archaeology at the museum, this will end with new strategic directions and new opportunities.

One of the main foci for the new Iziko Museums was to redress the imbalances of the past. The way this was approached in terms of maritime archaeology was to start an investigation to find the wreck of the Dutch East India Company slave ship *Meermin* (1766) (Boshoff 2003, 2018). Another feature of this project was that it was one of the first maritime archaeology projects funded by the National Lotteries. The other major project funded by the Lotteries was the National Survey of Underwater Heritage around the coastline initiated by the successor of the National Monuments Council, the South African Heritage Resources Agency (SAHRA).

In 2005, John Gribble left SAHRA and was ably succeeded by Jonathan Sharfman. Another important development at SAHRA was the creation of a second permanent post. Sharfman negotiated successfully funding from the Dutch

government and with their representative, the Centre for Heritage Activities, started a skills development project to promote underwater cultural heritage. This project uses the Nautical Archaeology Society courses as the basis for running annual field schools.

The *Meermin* project eventually evolved into a partnership with the George Washington University, the US National Park Service's Submerged Resources Center, and SAHRA as the African Slave Wrecks Project (the name later changed to the Slave Wrecks Project) funded at the start by the Ford Foundation (Lubkemann et al. 2008). Besides looking at slave shipwrecks, the project also investigated ways in which archaeology could be sustainable in the developing world mainly by considering the implementation of the SAVE (scientific, academic, volunteer, and educational) tourism concept developed by the George Washington University. The *Meermin* project also produced the first traveling exhibition on maritime archaeology in South Africa as well as a documentary, *Slave Ship Mutiny*, produced by Off the Fence Productions and screened on PBS network in the USA. Currently the Slave Wrecks Project is moving into a new phase with the addition of new partners in the form of the National Association of Black Scuba Divers and the new Smithsonian's National Museum of African American History and Culture by investigating what is believed to be the Portuguese slaver *Sao Jose* (1794) (NCD 1794). This project has led to an exhibition in the new Smithsonian's National Museum of African American History and Culture in Washington, DC, that opened on September 24, 2015, and has had to date (2018) more than four million visitors. In 2015 the *Sao Jose* project successfully bid for a grant from the US Ambassador's Fund for Cultural Preservation to upgrade the conservation laboratory at Iziko and to do the first environmental study of a historic shipwreck on the African continent.

As the new century progresses, there is much hope for maritime archaeology in South Africa. The resumption in 2011 of old projects like the investigation into seal hunting sites on Marion Island, the investigation into the slave ship *Sao Jose*, the development of a world-class conservation facility, and the training of new young nonwhite and female archaeologists undertaken by Iziko and SAHRA help to steer maritime archaeology in South Africa into new and exciting directions that will hopefully establish a unique niche in the world of archaeology.

South Africa: Maritime Legal Management

John Gribble[1] and Jonathan Sharfman[2]
[1]Sea Change Heritage Consultants Limited, Hale, Hampshire, UK
[2]African Centre for Heritage Activities, Cape Town, South Africa

Introduction and Definition

The management of maritime and underwater cultural heritage in South Africa has come a long way since legal protection was first given to historical shipwrecks in the late 1970s. Legislators and managers have learned to deal with thorny issues related to the ownership, relevance to changing heritage management priorities, public perceptions and expectations of maritime and underwater cultural heritage, and the significance (real and relative) of this heritage asset's constituent parts.

Shipwrecks have been the objects of particular official and popular attention and exploration since vessels were first wrecked on the South African coast. As early as the late seventeenth century, for example, the Dutch authorities at the Cape were involved in efforts to recover silver and other cargo from the wrecks of the English East Indiaman Joanna and the Portuguese vessel Nossa Senhora dos Milagros, both lost near Cape Agulhas. Much of this early interest was focused on contemporary shipwrecks and was salvage in the traditional sense of the concept. These historical salvage undertakings set a precedent for the next two centuries and had the effect of birthing and nurturing a popular perception among South Africans of shipwrecks, in general, as exploitable commercial resources. This perception drew no distinction between recent, contemporary wrecks and older sites with historical and archaeological value or significance, and the idea that historical wrecks had a wider meaning and value as precious archaeological windows into

our common past did not appear on the national radar until well into the 1970s.

Historical Background

A Rich Heritage Resource

South Africa owes its rich underwater heritage to its geographical position on the sea route around Africa from Europe to the East. More than 2,200 recorded shipwrecks, representing 36 different nationalities are recorded in South African waters. In addition to shipwrecks, South Africa's maritime heritage includes thousands of pre-colonial shell middens, numerous coastal cave sites, and, along the south coast, an assemblage of stone fish traps. A small collection of contact period rock art depictions of sailing vessels, which are believed to have been painted by the indigenous San and Khoi peoples, link European travelers and traders with South Africa's indigenous populations, while shipwreck survivor camps and maritime infrastructure like lighthouses, harbors, and boatyards attest to the extensive and varied European maritime activities in the region.

Treasure and Tribulation

The VOC salvage operations of the seventeenth and eighteenth centuries were superseded in the nineteenth century by treasure hunting and the development of a common view of wrecks as a source of curiosities and saleable "treasure." If anything good can be said about both this early salvage work and treasure hunting, it is that the recovery of artifacts was limited and that the majority of wrecks around the South African coast remained out of reach of the available diving technology, undiscovered and undisturbed. This changed with the birth of the aqualung in the 1960s and widespread plundering ensued as divers were quick to harness the new technology to find and exploit the commercial potential of many wrecks. In a 20-year period prior to the mid-1980s, a number of wrecks with rich cargoes of specie, Eastern exports like porcelain, or non-ferrous metals were found and salvaged. Collectively, these discoveries and the resulting recovery of often spectacular artifacts, coupled with the tales of treacherous diving conditions and not a few great white sharks, captured and fed the public imagination, reinforcing the perception that shipwrecks were no less than a source of treasure, to be recovered by those daring and intrepid enough to go out and help themselves. The significance of the wrecks plundered during these years, in as much as it was considered at all, was measured almost exclusively against their commercial potential. The absence of an argument for the heritage value of these sites simply entrenched South African public perceptions of the meaning and value of wrecks further.

The legal position of wrecks for much of this period was a further contributing factor in molding and entrenching the public and official view of shipwrecks. By 1969, coastal and maritime-related pre-colonial archaeological sites were protected by the National Monuments Act, by the inherent ethics of modern archaeological practices, and by virtue of them having little commercial value, but legislative protection for wrecks as a heritage asset was still some way in the future. Although a variety of domestic legislation did apply to historical wrecks, it can be argued that it was aimed primarily at dealing with contemporary or modern wrecks and was only incidentally applicable to historical wrecks (Van Meurs 1980). Nowhere was it "stated or suggested that any significance should be attached to wrecks known to be of historical and/or archaeological interest, or that such wrecks should be specifically protected" (Van Meurs 1980: 3).

For archaeologists, the immediate impacts of this period of rapid exploration and the discovery of many wrecks were negative. There was no professional archaeological diving capacity in South Africa and archaeologists had no access to these sites or material, except where they were above the water or when material had been recovered by divers. Although some divers did involve archaeologists and museum scientists in their projects (Jobling 1982; Maggs 1984), this was the exception rather than the rule and in most instances was aimed primarily at obtaining advice on artifact identity, and hence value, rather than because there was a real interest on the part of the divers in the archaeology of the sites in question.

Acceptable archaeological standards of excavation and recovery were generally not employed, detailed site recording was seldom carried out, site records were not generally made, and the publication of results seldom occurred (and then usually only selectively).

It would be disingenuous to completely disregard research carried out by salvage divers. Many did undertake historical investigations into their sites of interest, but this research was usually limited and generally fell into two broad categories, neither of which addressed the archaeological interest or significance of the sites concerned: initial research centered on identifying the location of a particular wreck, which usually fell short of examining the contemporary historical context in which the events occurred or the wider impacts of the wreck itself or the individuals involved on South African history, and research which revolved around the recovered artifacts. This was also limited and generally stopped short of examining relationships between artifacts or drawing inferences about the people or life aboard the ship and was purely descriptive.

In the final analysis, these activities were like any commercial operation, driven by profit. This meant that only certain shipwrecks and object types were targeted by divers. Wrecks that did not fall into the "treasure ship" category – slave ships, local coasting traders, or whaling vessels, for example – were unlikely to be profitable and were largely ignored. The same was true for artifacts forming the archaeological assemblages on "treasure ships." Only those of potential commercial value were of interest. The rest were ignored or discarded on site or, where recovered, offered to museums. The net result of much of the interest in South Africa's historical shipwrecks between the 1960s and late 1980s was the unquantifiable loss of archaeological and historical material and information as sites fell victim to often indiscriminate commercial salvage. In addition, the significance of this national maritime heritage was being shaped and determined by the small group of individuals who were seeking to profit from it, and this reinforced the already-skewed picture of South Africa's maritime history and heritage and its real significance to the nation and the world.

Legal Protection: National Monuments Act

As the scale of the hugely cosmopolitan underwater archaeological record in South African waters gradually became clear to archaeologists and historians during the 1970s, an appreciation of its true significance and heritage value began to coalesce. This was particularly the case among those working at coastal museums who were the first to see what was being recovered as divers approached them for artifact identification and valuation (Bell-Cross 1980; Gribble 1998). Archaeologists were slower to act on the potential of shipwrecks. The traditional preeminence in South African archaeology of pre-colonial studies meant that with few exceptions (e.g., Jobling 1982; Maggs 1984; Smith 1986), little archaeological interest was shown in colonial period (post-CE1652) archaeology and what lay beneath the waves until the mid-1980s. The national statutory heritage body, the National Monuments Council (NMC) was also slow to engage with underwater heritage and, in the absence of a stated national policy of cultural heritage protection, appeared unwilling to confront the Pandora's Box of legal, ethical, and heritage-related issues the escalating discovery and commercial exploitation of shipwrecks had opened.

Broad national heritage legislation had been introduced in 1969 in the form of the National Monuments Act (28 of 1969). The Act contained the seeds of a national policy of cultural heritage conservation, but it was not until a decade later, in 1979, that a national cultural heritage policy that was "morally and legally justifiable" (Van Meurs 1980: 6) was crystallized, defined, and made plain in an amendment to the Act. This amendment stated that: "The object of the [National Monuments] Council shall be to preserve and protect the historical and cultural heritage, to encourage and to promote the preservation and protection of that heritage and to coordinate all activities in connection with monuments in order that monuments will be retained as tokens of the past and may serve as an inspiration for the future" (Section 2A, National Monuments Act No. 28 of 1969). This amendment (Act 35 of 1979) also included the introduction of protection for historical shipwrecks. Section 10 gave the relevant

minister the power to declare as a national monument any wreck over 80 years of age which was considered to be of aesthetic, historical, or scientific value or interest (Deacon 1993).

Although the process for declaring wrecks proved to be flawed and difficult to implement, the 1979 inclusion of historical wrecks within the National Monuments Act was a critical moment in underwater heritage management in South Africa. For the first time wrecks could be legally protected. More importantly, however, this was the moment when the legal position and heritage view of historical wrecks shifted and they gained a new status and significance as heritage assets. Ironically, it was political pressure from a group of commercial salvors to protect their rights on two historical wrecks – the Santissimo Sacramento and the Dodington, both found near Port Elizabeth in the late 1970s – that was the catalyst for the introduction of this first legislative amendment, and the drafting of what was the first heritage position paper on historical shipwrecks, by the historian at the Port Elizabeth Museum (Nash 1977). This was also the moment when shipwrecks became a contested resource in South Africa. Until then, archaeological interest in wrecks had been minimal and the salvage and diving communities felt that they had both legal and moral primacy on the wrecks around the South African coast. They felt that the amendment constituted an intrusion of heritage interests into their previously exclusive domain.

Despite the inclusion of protection of shipwrecks in national legislation, there were still no diving archaeologists in South Africa, and the salvage community were quick to point out that archaeologists had no experience or understanding of the often challenging physical realities of working on underwater sites on the South African coast. They also accused archaeologists of being out of touch with reality, with rarefied and unrealistic views of what wrecks represented born of too much time spent in their academic ivory towers. In many instances this view still prevails within the South African salvage community. It has also been argued that modern South Africa has historically always tended to look inland and that, as a result, the national psyche has never fully engaged with South Africa's maritime history and underwater heritage. This influenced the nature of activities directed at the shipwreck record and may be responsible for the attitudes displayed by many South Africans towards historical shipwrecks (Brown 1987). These public sentiments and attitudes have, to some extent, guided the actions of the National Monuments Council and the policy frameworks developed for the management of South Africa's historic shipwrecks.

The NMC Grapples with Significance

Establishing and promoting the archaeological and historical significance of South Africa's underwater heritage was a major challenge for the heritage sector during the period between the 1960s and the late 1990s, and it is clear from documents of the period that the NMC was grappling with its own view of wrecks and their significance. For example, shortly after 1979, while acknowledging that the cultural value of wrecks increases with their age, the NMC also expressed the view that the wrecks around the coast were generally not part of South Africa's cultural heritage but that of the flag state concerned, such as Portugal, the United Kingdom, or the Netherlands (Rudner 1986). Furthermore, the NMC argued, the majority of these wrecks were wooden ships smashed to pieces during violent storms and that they therefore consisted only of scatters of artifacts spread over large areas of seabed. Therefore, went the argument "only the objects themselves are of value and should be salvaged before they are completely destroyed by chemical action, sand abrasion, . . . or by treasure hunters who constitute the greatest danger to them" (Rudner 1986: 2). In the NMC's view, therefore, the significance of these sites was tied firstly to "the objects themselves, [and] secondly, with the distribution on the seabed" (Rudner 1986: 2). Encouragingly the NMC did, at this stage, identify treasure hunting as a key threat to shipwreck sites.

From the contradictory nature of the elements of the NMC's de facto policy towards wrecks, it seems clear that the Council was battling to get to grips with this new and unfamiliar heritage asset. It was struggling to reconcile heritage

conservation objectives with pragmatic day-to-day management considerations, all within a foggy legal landscape, and was having its first experience of the sort of unhappy salvage versus conservation balancing act that has and still does characterize national shipwreck management policies in many parts of the world. Not surprisingly, the NMC's position on the value of the underwater cultural heritage was opposed by archaeologists and historians who viewed wrecks as sensitive archaeological sites and an important national cultural asset. As far as they were concerned, the investigation of maritime archaeological sites had to proceed on the same terms that applied to terrestrial archaeology (Deacon 1985) and argued that no disturbance of these sites should be permitted by the NMC until adequate national maritime archaeological expertise was in place (Rudner 1986).

During the late 1970s and early 1980s, the repeated use in official documents of terms like "salvage" and "scientific salvage" in relation to activities on, or aimed at wrecks, including archaeological work, is a clear indication that wrecks were not yet being considered to be archaeological sites by the authorities. At the same time, it is evident that after 1979 a clearer view of the nature and importance of South Africa's archaeological record, including wrecks, was developing within the NMC and the South African heritage sector. For example, it became clear from the Parliamentary debate on the 1979 amendment to the National Monuments Act that the legislation proposed did not deal comprehensively with the issues relating to wrecks. As a result, an interdepartmental Government Committee was appointed by the Cabinet to "investigate the preservation and protection of shipwrecks and their contents with a view to possible new legislation . . ." (Department of Transport 1983: 1). The Committee had the best interests of shipwrecks at heart and certainly did a good deal to ensure their protection. However, it was composed exclusively of government bureaucrats with non-archaeological views of what contributed to the significance of underwater cultural heritage sites. It is revealing that in one instance the Committee stated: "It is unacceptable . . . that a wreck which is still lying on the seabed or even on rocks or on the shore . . . be declared a national monument. The wreck cannot be attended to in such a condition, neither (sic) can it be cleaned, repaired or safeguarded and above all, it cannot be of value to the general public" (Department of Transport 1983: 21). This view of what constituted a national monument is clearly based on the traditional definitions of such monuments, drawn from the built environment.

Site significance also did not drive the NMC's attempts to protect underwater heritage in the 1970s and 1980s. Exerting control over activities aimed at wrecks drove protection, rather than the heritage significance of the sites themselves (Brown 1987). This changed in a NMC policy decision in the early 1990s in terms of which the date 1850 "should be taken as the date to divide the ships of higher historical and cultural interest from the later, less significant iron ones" (Brown 1987: 1). Although this division has its obvious flaws, it can be read as a genuine attempt to engage with the archaeological asset and make a clear statement of value about the remains of earlier, wooden sailing vessels. Following this decision, the NMC only issued permits for activities on pre-1850 wrecks in exceptional circumstances.

Archaeology Begins to Make a Mark

For much of the period discussed above, archaeological interest and involvement in underwater heritage-related work was reactive, driven by the need to have archaeological oversight and guidance on what were, in essence, licensed salvage projects. Only during the late 1990s did a change occur, partly the result of a fledgling maritime archaeological capacity but also because of tighter legislation and the NMC's engagement with, and commitment to, managing historical wrecks as part of the nation's cultural heritage. South Africa's first maritime archaeological appointment was a teaching and research post created at the University of Cape Town in the late 1980s. At about the same time, the former South African Cultural History Museum (now part of the IZIKO Museums of Cape Town) also employed its first maritime archaeologist. The

NMC followed in 1993 when it began the compilation of an inventory of historical shipwrecks in South African waters (Gribble 1996). A temporary post of maritime archaeologist was created to develop this database and 3 years later the Council confirmed its commitment to underwater heritage by making the post permanent.

This small core of professional maritime archaeologists was the catalyst for a number of research and conservation initiatives, like "Operation Sea Eagle," a major interdepartmental underwater survey of the waters within one nautical mile of Robben Island undertaken in 1990/1991. This early foray into the holistic management of shipwreck sites took place under the joint auspices of the government departments then responsible for the management of the island and aimed to provide an assessment of its underwater cultural resources at a time when its post-apartheid future was being considered (Werz and Deacon 1992; Werz 1993). Other early areas of research pursued by South Africa's maritime archaeologists include the archaeology of sealing and whaling, which begun with a project to document seal-hunting sites on South Africa's sub-Antarctic Prince Edward Islands (J. Boshoff, personal communication; Boshoff et al. 1997). Work continues on this project and it is also anticipated that it will in future be expanded to include a survey of coastal whaling sites within South Africa.

Key Issues/Current Debates

In 2000 the National Monuments Act was replaced by the National Heritage Resources Act (Act 25 of 1999), which established the South African Heritage Resources Agency (SAHRA). SAHRA's maritime archaeologists have worked hard to change and expand public perceptions of maritime archaeology and to develop a new national understanding of the significance of underwater heritage. The new legislation has facilitated this new focus by providing the same clear level of protection to maritime sites as had been given to terrestrial archaeological sites since the 1980s. One area of the new legislation which has and continues to be an issue for underwater heritage is the provision which allows the controlled sale and export of archaeological artifacts. Included in the Act to control the movement and export of collections of archaeological material in private hands, this provision has been seized on by treasure hunters to question SAHRA's de facto post-2000 ban on historical shipwreck salvage.

Although the Act does not state unequivocally that the commercial exploitation of historical shipwrecks is banned, the inclusion of wrecks under the definition of "archaeological" in the legislation and the fact that ownership of all archaeological material is vested in the State effectively remove shipwrecks and their contents from the realm of commercial salvage. After 2000, SAHRA began closing the door on the commercial salvage of historical wrecks and in 2003–2004 SAHRA introduced a Shipwreck Policy aligned with the UNESCO Convention on the Protection of Underwater Cultural Heritage and the Annex attached thereto. The Shipwreck Policy essentially outlawed commercial salvage and the issuing of salvage permits for any wreck older than 60 years by requiring the application of the rules of the Annex to any future shipwreck investigations. By 2005, however, SAHRA was forced to repeal its Shipwreck Policy after legal advisors adjudged it to be in conflict with the National Heritage Resources Act of 1999 and its associated regulations and suggested a return to the permitting system introduced in the 1980s. As a compromise a transition period was agreed, during which SAHRA undertook to consider salvage-based applications. A revised National Shipwreck Policy has been prepared by SAHRA and the national Department of Arts and Culture (DAC) but remains unimplemented as DAC considers the budgetary and others costs of implementation. The new Act has put the onus on the archaeologists at the SAHRA and other institutions to promote maritime archaeology and underwater cultural heritage, its significance, and the reasons for protecting of maritime sites. It is now up to archaeologists to develop and encourage a public

view of scientific investigation and excavation of this national, publically owned asset as a better alternative to salvage for the personal gain of a few individuals. To do this, maritime archaeologists in South Africa must wean the diving community and the wider public off the traditional, salvage-driven perceptions of historical shipwrecks and persuade them that the real attraction, value, and importance of these sites and objects lie in their archaeological and scientific potential and the human stories they can tell. While legislation can offer wrecks legal protection, real protection – the type that will stop treasure hunting and looting – can ultimately only come from a changed public view. The focus for SAHRA in recent years, therefore, has been on changing attitudes and expanding the public understanding of underwater heritage though education and participation. Its maritime archaeologists have thus been working to create an inclusive culture around maritime and underwater cultural heritage, and this has been marked, inter alia, by projects and work that reflect the heritage value and significance of South Africa's underwater heritage – in contrast to the historical situation where value and significance was defined and driven by a small group whose primary interest in underwater heritage and motivation for being involved was commercial. Projects aimed at the less well-publicized aspects of South Africa's underwater archaeology have been set up and brought into the public eye through the media. These projects include two National Lottery-funded initiatives – the National Survey of Underwater Heritage and the Meermin Project – and a capacity-building program funded by the Dutch government.

International Perspectives and Future Directions

Heritage legislation, the National Survey of Underwater Heritage, and the Dutch-funded Maritime Archaeology Development Programme appear to be bearing fruit with noticeable changes in attitudes towards underwater cultural heritage. Although progress has been slow, divers and others who use these sites are more aware of the legislation and the reasons for it and have taken a greater interest in protection of underwater sites. Local communities living near wreck or maritime heritage sites have begun to take ownership of these sites and are reporting transgressions against the heritage more often. The Department of Arts and Culture is also considering the ratification of the 2001 UNESCO Convention, and there is increasing political interest in underwater cultural heritage.

From a heritage management perspective, archaeologists and heritage professionals are adjusting to their new roles. New initiatives for policing must be developed, including community policing, volunteer programs, and interdepartmental and interagency cooperation. Archaeological foci must change from the simple description of sites and artifacts to social and theoretical studies, and new ways must be found to fund maritime archaeological work, develop and increase capacity, and protect sites. To be successful, South Africa must begin to look beyond its own shores: its underwater heritage assets represent a multicultural and multinational shared heritage, and for effective future management, it is going to be essential therefore to look more widely at cooperative projects, international partnerships, and global initiatives.

South America: Lithic Industries

Antoine Lourdeau
Departamento de Arqueologia, Universidade Federal de Pernambuco, Recife, PE, Brazil

Introduction

The lithic industries of South America constitute a privileged archaeological record for the reconstruction of the modalities for human settlement of this region, relatively recent on a global scale, and the techno-cultural identities of the human groups who occupied it.

Often focused on bifacial projectile points, studies have nonetheless demonstrated an impressive range of variability in knapping concepts and technological solutions employed by the first inhabitants of this vast and varying landscape. Our knowledge of such techniques is not yet as refined as in other parts of the world. It is, however, already possible to identify the broad developmental lines of these lithic industries and to distinguish techno-cultural groups relatively well defined in time and space.

Definition

The lithic assemblages form the principal evidence of the very first human activities on the continent, probably starting in oxygen isotope stage 3, less than 50,000 years ago. Use of stone persisted until contact with the first European colonists at the beginning of the sixteenth century and often even after. The major originality of South American prehistory is the expansion of human settlement of this subcontinent, linked in part to two elements: (1) the relative isolation of this area, flanked by two vast oceans and accessible by land via a narrow isthmus and (2) the recent date, on a global scale, of the first human presence. The approach to the history and evolution of techniques on the continent is thus limited to a much more restrained timescale than elsewhere. These techniques underwent a unique sequence of development, which appears to have been linked as much to local dynamics as to external contributions.

From a strictly technological viewpoint, the main characteristics of the South American lithic industries are common to all prehistoric lithic production systems. The broad families of knapping techniques are found in all of the industries in South America: shaping, which can be bifacial or unifacial; reduction processes, represented by concepts considered little developed but also sometimes by laminar, lamellar, and Levallois concepts. Similarly, most of the known knapping techniques are represented here: direct stone percussion, bipolar percussion on anvil, direct organic percussion, and pressure flaking. It is thus with the same methodological kit used elsewhere that these lithic industries are examined and in particular by technological, techno-functional, and use-wear approaches.

However, the South American lithic production systems are not devoid of originality, because while lithic knapping concepts are finite, methods of exploitation of stone and especially knapping objectives, that is, the intended tools, can be represented by a number of aspects. In the specific context of South American prehistory, new technological solutions were invented. These particularities are discussed below.

Historical Background

Apart from rare ethnographic comments by chroniclers and the first European voyagers, the earliest references to the South American lithic material date to the mid-nineteenth century. As for most of the continents at that time, what really matters is not the lithic artifact as evidence of a specific technological activity but rather as the marker of a human presence in the distant past. This is the case, for example, for the pioneering research of the Danish intellectual P. Lund, who sporadically mentioned the lithic material recovered during his excavations around 1840 in the

Lagoa Santa region (Brazil) to support his discoveries of human remains found in stratigraphic layers assumed to be very old (Fig. 1).

It is also in this context of debate on the antiquity of human occupation of the Americas that F. Ameghino would use, at the beginning of the twentieth century, complementary to the bones discovered, the lithic material recovered on the pampas to propose his hypothesis of an Argentine origin for our species. This theory was vigorously discussed, notably by A. Hrdlicka, but the positive effect of this debate led to more detailed analyses of the lithic material. As a direct result, one of the first rigorous and in-depth studies was carried out by W. Holmes, on artifacts collected by A. Hrdlicka during surveys along the northern coast of Argentina. These were principally cobble industries, transformed by pecking, percussion, or knapped using the bipolar on anvil method. This material, coming mainly from surface collection, is of undetermined age. The 1912 publication presents many innovative elements: in addition to an initial typology and many illustrations of excellent quality, we find comments on the criteria for raw material selection by the knappers and on the modes of production for stone tools, with some experiments on knapping techniques (Hrdlicka 1912).

South America: Lithic Industries, Fig. 1 Distribution map of the archaeological sites mentioned in the text. 1: Taima-Taima, Venezuela; 2: El Abra, Columbia; 3: El Inga, Ecuador; 4: Paiján; 5: Guitarrero cave; 6: Telarmachay; 7: Pikimachay; 8: Asana, Peru; 9: Pedra Furada and Sítio do Meio; 10: Lagoa Santa region; 11: Serranópolis; 12: Santa Elina, Brazil; 13: Monte Verde, Chile; 14: Cerro La China; 15: Los Toldos, Argentina; 16: Fell's cave; 17: Cabo San Vicente, Chile

It is only in the 1930s that the lithic material was studied in its own right, as evidence of prehistoric human identities and activities. One of the key figures in research at this time is J. Bird, who excavated main sites in Patagonia (Bird 1988). Based principally on bifacial projectile points that he discovered, Bird established a typology structured in successive chronological phases. In 1950, with the invention of radiocarbon dating, Bird's studies took on a new dimension: the dates obtained for the earliest phase that he defined were older than 10,000 years at Fell's Cave, dates much older than anticipated. Considering the settlement theories and data obtained from North America, these dates would imply a very rapid movement of the initial occupants to the south. Following these discoveries, the lithic industries found in South America would have a tendency to be systematically studied through the filter of what is known in the north. In the South American material, one would thus look for markers typical of the Clovis culture, assumed to be the oldest in the Americas. The Clovis point, a bifacial foliate armature with a fluted base, is the emblematic element of the first assumed industries in North America. It is not found in South America, but the discovery of bifacial projectile points with small thinned tang (called "fishtail" points) by J. Bird in the early layers at Fell's Cave suggested a southern adaptation of the North American point. This hypothesis was all the more followed when it was seen that fishtail points were not confined to Patagonia but were also common further to the north, in the Pampas (Fig. 2) and also on the Pacific coast in Peru and Ecuador, for example, at the site of El Inga.

This view of the Clovis culture as the sole origin of all human (and thus technological) manifestation in the prehistory of the Americas would dominate throughout the second half of the

South America: Lithic Industries, Fig. 2 Two fishtail points from Cerro La China, Argentina. (From Zárate & Flegenheimer, 1991: 288, detail) (Courtesy of Nora Flegenheimer)

twentieth century and even today still have its supporters. However, in the 1960s and 1970s, a few dissenting voices made themselves heard. Based on the position maintained by A. Krieger, according to which the first American lithic industries lacked bifacial projectile points, A. Bryan argued that South American industries with projectile points at the Pleistocene-Holocene transition and during the Early Holocene resulted from evolution from a local Pleistocene substrate (Bryan 1999). He thus argued against the idea that all South American lithic technology was due to migration from the north.

Such "liberation" of South American prehistory from its influence from the north would open the field to consider the variability within the lithic industries, both spatially and diachronically. From then on, true technological groups would be described, not only on the basis of bifacial projectile points, thus revealing the considerable variety of industries within South America. So, in the 1960s–1970s, the Abriensian would be defined by G. Correal and T. Van der Hammen, later termed the Edge-Trimmed Tool Tradition by W. Hurt, in central Colombia, the Paijanian by *P. ossa* in northern Peru, the Andean Biface Horizon by E. Lanning in the Andes mountains, the Itaparica Tradition by V. Calderón and then P. Schmitz in central and northeast Brazil, the "Cerca Grande" complex by W. Hurt and

O. Blasi at Lagoa Santa, the Umbu and Humaitá Traditions by E. Miller in southern Brazil, the Toldensian and the Casapedrensian by O. Menghin, and then A. Cardich in Argentinean Patagonia, to cite only a few (Dillehay 2000; Lavalleé 2000).

As on the other continents, the approach to the lithic industries in South America would undergo significant changes during the 1970s. Very generally, two broad trends developed. The first, influenced by the Anglo-Saxon school, is characterized by a new perspective with respect to the material and the questions that can be addressed by it. Cultural questions and definitions of technological groups take second place in particular to processes, spatial organization, social evolution, and modes of adaptation to different environments. Lithic raw material analyses, their nature, provenance, and mode of circulation, develop considerably, especially in Argentina. The second trend is the result of a methodological approach rather than a change in perspective. Questions of a cultural order remain at the heart of research problems, behavioral approaches not being as excluded as in the first trend. This approach is based on the observation according to which the typological approaches to the material thus far are not sufficient for a complete understanding of the lithic material. The definitions of cultural groups by a simple list of types are seen as scarcely operational. A new, more technological, approach to lithic production was thus developed. Research is no longer focused only on the tools made but also examines the technological processes and the knowledge and know-how applied by the knappers. This approach, coming out of French research on lithic technology, is particularly heuristic for the interpretation of the differences observed between collections. Technological studies thus enable reevaluation of the validity of the previously defined cultural units and rationalization of the increasingly marked trend during the 1970s to create a new group, a new "tradition" or "culture" at each new site discovered. We note, among the studies done in this perspective, those of C. Chauchat and J. Pelegrin on the Paijanian industries (Chauchat et al. 2004), H. Nami on the Levallois debitage in southern Patagonia and Tierra del Fuego (Nami 1992), and more recently, the analyses of N. Pigeot, also on Patagonian material (Pigeot 2003).

With the rise of local research centers, the discovery and analysis of lithic assemblages have considerably multiplied in South America over the last two decades. Approaches remain most often more typological than technological, but knowledge has improved in the broad regions previously unknown, and the chronological framework for the analyses has expanded to include the periods as recent as the end of the Pleistocene and the Early Holocene. New methods to analyze the industries has also seen significant development, such as the techno-functional analyses in Brazil, which enables the finished products (tools) to be once again included in the discussion of technological processes and intentions (Fig. 1).

Key Issues

What Do the Points Tell Us (or Not)

Throughout the Americas, projectile points are the most commonly exploited artifacts in the lithic assemblages to address the questions of human settlement, spread, and circulation during prehistory. The contours of such points enable definition of types, for which one attempts to perceive development through time and to interpret the meaning of their distribution across space. To the north, this typological approach has been proven and the chronological and geographic limits of the different categories of bifacial foliate points (Clovis, Folsom, Plano, etc.) can be clearly followed. In South America, attempts at typology on a continental scale are not lacking, but apart from a few zones, this approach has not been particularly fruitful. This may be due first to the near complete absence of points in vast regions, such as central and northeast Brazil. In addition, the defined types often have a limited spatial distribution and are represented by fairly low frequencies.

Fishtail points are, however, an exception. These short bifacial points, with convex edges and a tang often thinned by what is interpreted as a small flute, have been found in Argentina,

Chile, Peru, and Ecuador, in contexts dating to the Pleistocene-Holocene transition (Fig. 2). This flute has led to many publications regarding the possibility of the relationship between the fishtail point and the Clovis point. Dominant in the first half of the twentieth century, this interpretation of the fishtail point as a development of its homologue to the north is today far from being unanimous. The only argument of the "flute" is quite weak since technological studies have demonstrated that, in most cases, these small removals thinning the tang were made during the shaping phase of the piece and not at the end of the production phase. They are thus not truly flutes or grooves. Therefore, several authors attribute a possible South American origin to this type of point (Politis 1991), and some even argue that there is not a single fishtail point type but several, each with its own regional origin and that their similarity is due to morphological convergence (Borrero 1983 cited in Nami 2010). Many other types of projectile points have been defined in South America, such as the "El Jobo" lanceolate point in Venezuela, the long-tanged point of Paiján type on the northern coast of Peru, and the Ayampitín point, one of many Andean point types. These artifacts were made by bifacial shaping with soft percussion, sometimes completed by a phase of pressure flaking. But fishtail points, probably the most studied type and for which the spatial distribution is the largest, are particularly representative of the limited potential of projectile points for approaching questions going beyond a regional scale. The principal danger of all morphological interpretations is the convergence of forms. To prove the existence of a historical link between two types of artifacts, one may ask, "Is the simple criterion of form really valid?" These variations between projectile points indicate limited technological differences, since the technical knowledge and skills needed are overall the same regardless of the kind of point produced and, excluding a few specific cases, the functional intentions appear to be similar. This variability may be linked to technological procedures related to different hafting modes. However, these differences may rather evidence, at least in part, stylistic variability, in other words, relatively versatile traits of technological productions that are difficult to follow for prehistoric periods. These traits are not necessarily markers of significant differences between the human groups studied.

The development of technological approaches to lithic assemblages has shown that, in order to estimate the degree of difference between several assemblages, it is necessary to study them at the scale of shaping concepts and not be limited to simply the forms resulting from application of such concepts. The profusion of publications on projectile points has had a tendency to overshadow the rest of the lithic industry, which forms the overwhelming majority of material recovered, and represent a potential often little exploited to study the development of techniques on the continent and the definition of cultural groups.

Industries of the First South Americans

Often mentioned to question their age or to discuss their human origin, South American industries dating to the Pleistocene are more rarely examined from a technological view. The earliest lithic productions discovered would date to oxygen isotope stage 3. At Pedra Furada (Brazil), a production based solely on quartz and quartzite cobbles has been found in layers dating between 50,000 and 15,000 BP (Parenti 2001). These cobbles were shaped into different classes of massive tools by uni- or bifacial removals and were knapped in the aim of obtaining flakes. Such reduction was organized into short series of removals, generally unidirectional. Bipolar on anvil reduction has also been identified. Most of the flakes obtained are cortical and sometimes retouched. At Santa Elina (Brazil), the toolkit from stratigraphic assemblage III, dating to around 25,000 BP, was obtained from limestone plaquettes and flakes (Vilhena Vialou 2005). The latter were produced via simple reduction. The supports were sometimes retouched, generally by abrupt retouch, in order to create concave or denticulated edges. In layer MV-I at Monte Verde (Chile), dated to around 33,000 BP, a few pieces of knapped basalt were found, including a core showing the production of small flakes in unidirectional series.

These early lithic industries are thus always very simple. The tools are essentially made of natural untransformed volumes (cobbles or plaquettes) on which only the edges were retouched. Tools are also sometimes made on flakes. These come from reduction processes in which the cores were subject to short series of removals without prior preparation. Shaping is absent in these industries.

Sites dating to the end of the Pleistocene, between 15,000 and 12,000 BP, attest in particular the appearance of bifacial shaping. This appears to be associated from the start with the production of projectile points, as at Taima-Taima (Venezuela) and layer MV-II at Monte Verde (Dillehay 1997). In these two cases, lanceolate bifacial points were found. These are elongated, untanged, shaped by soft percussion, and traditionally associated with the El Jobo type. The production of tools on natural supports (cobbles or plaquettes) and on flakes obtained by short series is still present, either in association with shaping activities, as at Taima-Taima and Monte Verde, or exclusively, as at Sítio do Meio (Brazil) and Pikimachay (Peru). Monte Verde is further set apart by the discovery of ground stones, including two small grooved cobbles.

Flaking Systems and Main Technocomplexes

The objective here is not to list, site by site, the lithic material produced. This section being thematic, a purely chronological organization is not presented but rather an overview based on the principal technological systems encountered throughout South American prehistory. This is, of course, a very general and fragmented summary, the reflection of current knowledge on this topic.

Ubiquitous "Simple" Reduction Process

Flake production from "simple" reduction processes are found throughout the continent, in all time periods and in significant proportions during South American prehistory. Such omnipresence has, in a way, slowed detailed studies of the lithic industries. Indeed, what can be said, from a typological viewpoint, of an industry where no standardization of products can be clearly seen? A technological approach to these industries, and in particular to the cores, enables the observation that reduction is structured in relatively short series, often unidirectional, in which the sequence of removals is based on naturally present criteria of convexity, without advance preparation of the block of raw material. It is possible to differentiate groups of methods by the mode of core management: number of flakes produced by series, organization of removals within a single series, number of series per block, and organization of these series on a single block (Fig. 3). Knapping techniques also offer a second degree of differentiation of the industries: all of this reduction is carried out by direct stone percussion, but some cores were exploited by launched percussion, without support, and others by bipolar on anvil percussion. Bipolar on anvil percussion is effectively common through the continent, particularly when knapping small volumes.

Description of intentions, or the classes of intended tools, forms another criterion of variability for this type of production. This is without doubt the most significant criterion to isolate techno-cultural groups. For such industries without standardization of blanks, the typological approach, which aims to identify artifact classes based on form, is not suitable. Determination of flaking objectives must be done by a techno-functional analysis that combines tool production schemas, the volumetric structures of the tools, the functional potentials of their active parts, and modes of grasping or hafting. Such analyses, still rare, have enabled identification, for example, in central Brazil during the Early Holocene, of the systematic intent to create short tools with a concave or denticulated edge opposite a back on flakes produced by "simple" reduction (Mello 2005).

Regions Noted for the Development of Bifacial Shaping

The utilization of bifacial shaping is observed from the end of the Pleistocene in several regions of South America, in particular for the production of projectile points. In addition to these armatures, the use of bifacial shapes also enables the creation of a broad range of tools, varying as much as tools

South America: Lithic Industries, Fig. 3 Two cores from Serranópolis, Brazil. Reduction is structured in short unidirectional series, without advance preparation of the block of raw material. (Photos by A. Lourdeau)

on flakes. One of the areas notable for the development of bifacial shaping to produce a wide range of tools is the Central Andean zone. In several sites dating from the end of the Pleistocene to the Late Holocene, including Guitarrero, Telarmachay, and Asana in Peru, bifacial shaping constitutes a privileged mode of blank production (Lynch 1980; Lavalleé 1985). The different types of projectile points generally represent more than half of such production, but a varied toolkit is also sought. Bifacial artifacts that are not point have had a tendency to be considered, sometimes with reason, as point preforms abandoned during the production process. However, many of these are clearly finished tools, with edges prepared by fine retouch (Fig. 4). They are supports probably destined for different functions and are comparable in this sense to the "bifaces" (or "handaxes") known in the Old World in earlier periods. The Andean bifacial pieces are always associated, in the archaeological assemblages, with many unifacially retouched flake tools.

In southern Brazil, bifacial retouch is also a technological solution especially used to obtain tool blanks in archaeological assemblages of the Umbu and Humaitá traditions, dating from the Early Holocene to more recent periods (Hoeltz 2005).

"Complex" Reduction Methods Still Less Tangible

The existence of exclusively blade production has long been known in Patagonia, in particular in the Casapedrense layer at Los Toldos, in Argentina (Middle Holocene) (Cardich & Flegenheimer 1978). Yet the technological traits of this reduction process and its geographic extension and development through time are still difficult to determine, due to lack of technological studies of the collections. Some indices of this type of production are also mentioned for more northern zones, in northwest Argentina and southern Brazil (Hoguin 2012). Based on the available data, this is clearly a reduction system in which the entire core

South America: Lithic Industries, Fig. 4 Two bifacial artifacts form Telarmachay, Peru. (Drawings by C. Chauveau, from Lavalleé 1985: 170–171, detail) (Courtesy of Danièle Lavallée)

is structured to produce only blade, the angle and front being maintained during the production of these blanks. The block is at least partially prepared (presence of crests), and the technique used is hard or soft percussion. No pressure flaking has as yet been described in South America. "Blades" and "bladelets" are mentioned in several other regions, but, given the lack of detailed description of the cores, it cannot be excluded that such elongated blanks could have been obtained during non-elongated flake production.

Predetermined flake production from cores for which the volumetric structure is identical in all respects to the Levallois system in the Old World has been identified by H. Nami in Patagonia (Nami 1992). Levallois reduction, until then known in quite different geographic and chronological contexts, is present in Patagonia with the same variability as elsewhere: preferential and recurrent flake methods have been described by F. Morello at Cabo San Vicente, Tierra del Fuego (Morello 2005) (Fig. 5). For now, this reduction system is limited to the extreme southern tip of the continent, in contexts dating to the Late Holocene. Based on the traits of some of the published flakes, it could, however, extend across a broader area and go back to earlier periods.

Unifacial Shaping: An Original Technological Solution?

Unifacial shaping constitutes a fairly common mode of blank production in South America between the end of the Pleistocene and the mid-Holocene. This is a relatively original solution with respect to the history of lithic flaking techniques, situated between shaping and reduction. The procedure consists of shaping large flakes only on their dorsal face, while the ventral face is never directly modified. The volumes obtained in this way are generally elongated, with an overall plano-convex section. Such pieces differ from flake tools with unifacial retouch by the fact that the removals after knapping clearly alter the initial volume of the blank and are not intended only to create or modify the active parts of the tool. Unifacial shaping is observed essentially in central and northeast Brazil in the Itaparica technocomplex (Lourdeau 2010). Detailed analysis of the Serranópolis collections have enabled determination that the tools obtained, often termed limaces, systematically have a symmetrical transformative part at one end, with a rounded, pointed, or transversal rectilinear delineation (Fig. 6). The analysis has demonstrated that these blanks were probably destined for several different functions

South America: Lithic Industries,
Fig. 5 Levallois cores from Cabo San Vicente, Chile. (**a**) and (**b**) Recurrent flake method; (**c**) Preferential flake method. (From Morello 2005: 40–41, modified) (Courtesy of Flavia Morello)

and a single piece could have several independent functional parts on the ends and/or the lateral edges. These are thus, like some bifacial pieces, supports for varied tools. Similar pieces exist further to the west, in Peru, Ecuador and Colombia, and to the south in Argentina, also dating to the Early and Middle Holocene.

This rapid overview of the main technological solutions that can be encountered in the South American lithic industries enables one to appreciate the significant variability in lithic production. One finds most of the concepts, methods, and reduction techniques known in other regions, but their position in time and space remains difficult to determine. To this can also be added certain uniquely South American practices, such as unifacial shaping, a practice that has not as yet been observed elsewhere.

International Perspectives

Despite a certain idea of isolation associated with South American prehistory, full understanding of the South American lithic industries requires an overall vision of these productions. Only such a broad perspective enables us to attempt to interpret the variability in the lithic industries,

South America: Lithic Industries, Fig. 6 Unifacially shaped artifacts from Serranópolis, Brazil. (Drawings by A. Lourdeau)

determine their local or external origin, and thus explain the dynamics of human settlement of South America.

One can consider the signification of the very first lithic industries here. They are still fairly poorly understood but are based only on natural volumes or blanks produced by simple reduction. These productions are fairly out of sync with the development of contemporaneous industries on other continents (with the exception perhaps of East Asia). Is this local development or should we look elsewhere for the origin of such production systems? One or the other of these alternatives involves in its turn many questions.

As for bifacial shaping, this technique appears abruptly in the form of projectile points without intermediary stages. Based on data for the development of bifacial shaping observable in other regions, its presence in South America could thus be interpreted as an external contribution, already at a certain stage of development.

Unifacial shaping, in contrast, appears to have had its own unique development in South America. A few examples of limaces have been mentioned in North America, but as yet nothing described is comparable to the productions in the Itaparica technocomplex. In Southeast Asia, the Hoabinhian is also known for its unifaces made on

cobbles. However, important differences exist between these and the South American industries with respect to concepts of volumes and tools.

The example of the lithic industries of South America, and the singular context of its prehistory, may in addition enable understanding of certain important phenomena for the global explanation of technology (Boëda 2005). How better to illustrate technological convergence, that is, the independent development of two similar flaking systems, than by the example of Levallois reduction in Patagonia? The lack of geographic and chronological continuity with the Levallois of the Old Word is so obvious that it excludes any hypothesis of diffusion. South American blade production, while still lacking detailed technological description, would appear to be another example of convergence.

Future Directions

The next few decades should be decisive for the study and explanation of the South American lithic industries. The creation of new research centers, as well as a return to detailed studies of the material (relatively neglected for awhile in favor of more general considerations) but with more rigorous methods, foreshadow a clear increase in technological analyses of the modes of blank production and the tools which are the objective of such reduction. These new studies, coupled with new dating programs (particularly by OSL), should enable refinement of the regional sequences and offer the possibility of reconstructing a general framework for the development of lithic industries on a continental scale. New approaches, particularly use-wear analysis, will widen the field of knowledge of this material.

South American Archaeology: Postcolonial Perspectives

Alejandro F. Haber
Escuela de Arqueología, Universidad Nacional de Catamarca & Consejo Nacional de, Investigaciones Científicas y Técnicas, Catamarca, Argentina

Introduction

Problematic Entrance as Entrance to the Problematic

A South American postcolonial perspective on any problem involves, first and foremost, a consideration of whether or not South America is a place from which it is possible to have such a perspective. If such perspectives are indeed postcolonial, this suggests two possibilities: (1) that they were later to a colonial experience or (2) that they were inspired by a

body of theory and assumptions designated as postcolonial. Those options are external because they could mean that the colonial experience is a thing of the past – thus post – or that postcolonial theory is something that you can embrace or reject as any other theory. However, that the colonial experience, on the one hand, was not surpassed by political independence and, on the other hand, is constitutive of subjectivity becomes immanent to the perspective and not external to it. Whether we call it postcolonial or otherwise, the colonial experience is immanent to the place of these theories. The postcolonial world, in this case, is more a pre-theoretical condition than a theoretical framework, i.e., more a condition of thinking, of knowledge, than a knowledge about a delimited field of content. Moreover, once introduced into theory, that postcolonial pre-theoretical condition is, at the same time, metatheory, i.e., it is theoretical knowledge about theory and its conditions. Finally, as knowledge about the conditions of knowledge, it leads through to the possibility of overcoming the conditions of coloniality, something which has been designated as a decolonial option.

If, even more, these South American postcolonial perspectives are given in the disciplinary framework of archaeology, two other issues must be weighed: (1) the object-history of archaeology established as prehistory, i.e., a historical narrative of a time without history, i.e., as an anomalous history, and (2) the importance of disciplining and institutionalization in the demarcation of the boundaries of the object-history, demarcation which is, at the same time, of the subjectivity of history.

Finally, if we try to make history of these perspectives – as this entry suggests – we could either consider history as a narrative of what happened objectively and externally or recognize from the beginning that history itself – its idea, its method, and its scope – is an integral and active part of colonialism and the conditions of possibility of postcolonial (and even decolonial) archaeologies in South America.

Key Issues and Current Debates

Colonial Designations and the Place of Theory

I shall begin with the first of the assumptions referred to in the preceding paragraph: that South America is a place from which a perspective on archaeology can emerge. This, again, leads to the colonial question, at least in two senses. It is clear that South America (or Latin America, or Ibero America, or Hispanic America, or any of the usual geographical categories) is the result of the history of colonial designations. America was not a geographical name or its real referent until 1507 when Martin Waldseemüller baptized it with the name of Amérigo Vespucci (what the Spaniards called then *the Indies*). At this point, it might be thought that this discussion is about a mere question of naming, and to some extent it is. It also happens that the act of naming has implications with respect to what is understood as the external reference to the name. For instance, America began to be *one* thing from that moment, i.e., a thing that was able to be designated by a single name. And, in addition, that thing that became America could, by the mere fact of the designation by European cartographers, be stated by its name from Europe (Mignolo 2007).

The designation of America, therefore, like any colonial designation, involved the appearance as one thing or category of what the name lawfully represented, as well as the appearance of a lawful enunciator of that thing. Whatever America is, then, becomes what is enunciated and written as such from the place of the colonial power, and this place becomes the place from where the colony is enunciated and written. Modern colonial bureaucracy is based on writing procedures, a technical device that needs, among other things, names for things in the world and people giving the names. Thus, the existence of both a proper name and a proper enunciator of the world out there targeted for appropriation is a material condition of modern colonialism. The colonial designation, being a mere question of names, is also a condition of the possibility of the realization of the desire of colonial expropriation. The things to expropriate – i.e., the colonized world – are lawfully enunciated by the colonizer and, as it follows, illicitly by the

colonized, who is possessor of a false knowledge and an imperfect language even to enunciate the world and the one's own body; such is the historical material condition of colonialism, or its dark face, *coloniality* (Schiwy and Maldonado-Torres 2006). This *differential constitution* of being and knowledge is one of the central tenets of postcolonial thought. That America has been, much later, a name appropriated by the United States for its self-designation has led to other designations arising to qualify the other America: South America, America of the South, and Latin America.

The existence of South America as a place of enunciation of a theoretical perspective on archaeology is closely linked to the self-awareness of South American archaeologists of their differential designation, i.e., of its constitution in the *difference* from colonial powers. But in the archaeological field, this self-consciousness has not been based in any postcolonial perspective but in the so-called Latin American Social Archaeology (LSA) of the 1960s and 1970s (Politis and Pérez Gollán 2004). This current, specifically inspired by historical materialism, has been perhaps the first to occur, more or less unified, with both a theoretical inspiration and a political sense (hence, it is *social*, beyond what each one understood as such in political terms) and a place from which to establish a new perspective (thus *Latin American*). This movement will not be outlined in any more detail here as other entries in this volume deal with its development.

Although the LSA continues to be a theoretical reference in Latin America (and also in Spain – Castillo et al. 2008 – as well as other countries), towards the mid-1990s the momentum of LSA was already reasonably diluted due to the growing hegemony of processual archaeology of North American origin and the anti-Marxism of the academic contexts in some countries of South America (particularly in the Southern Cone as a long-lasting effect of the military dictatorships of overt anti-Communist orientation and counterinsurgency action).

Also, the notion of a common South American belonging was not present anymore as an inspiration for theoretical reflection. In the mid-1990s South American archaeology was so dispersed that archaeologists from different South American countries read each other in European and/or North American publications. Moreover, it then seemed to be installed a disciplinary common sense of the banality of a local or regional perspective. In reaction to this there came the series of Meetings of Archaeological Theory in South America later known as TAAS (Funari et al. 1999). The meetings of Vitoria in 1998, Olavarria in 2000, Bogotá in 2002, Catamarca in 2007, and Caracas in 2010 were milestones in the emergence of exchange, research, mutual knowledge, and discussion, at a South American scale (Gnecco and Haber 2005). It was consolidated with the appearance of publications with continental scope, which were published on the continent by South American archaeologists, starting with the bilingual journal *Arqueología Suramericana/Arqueologia Sul-Americana*, to which *Revista de Arqueología Histórica Argentina y Latinoamericana* and *Vestígios Revista Latino-Americana de Arqueologia Histórica* were added. Thus, the beginning of the twenty-first century sees the recovery of the notion that South America can be a place from which an archaeological perspective can be enunciated. Indeed, the TAAS meetings and the South American publications have provided the forum for discussions about whether or not South America is a singular place from which knowledge about archaeology can be generated.

Peripheral and Critical Theory

In 1984, Trigger published an influential essay that proposed ways in which relations among nations gave rise to the archaeologies in each country. Colonial, national, and imperial archaeologies were influenced by the manner in which each country was globally related (Trigger 1984). The value of the cartography of Trigger was challenged explicitly (Olsen 1991) and implicitly (Funari 1989) from perspectives that characterized the geopolitics of archaeological knowledge in terms of the theories of dependency and the world-system, introducing the concept of *peripheral archaeologies*.

Pedro Funari (1989) characterized peripheral archaeology (particularly Brazilian) according to academic and social criteria. From an academic point of view, a peripheral archaeology is bilingual – and sometimes polyglot – while a central archaeology is monolingual. Multiple linguistic competence of the periphery also implies knowledge of theoretical bodies of various origins, regardless of the nationality of the authors at issue. A central archaeology, on the other hand, has a much more insular and self-sufficient behavior (Funari 1989). This vision of the conditions of the peripheral archaeology in comparison to central archaeology contrasts sharply with common visions, according to which the central archaeologies are role models to peripheral archaeologies. There is, then, a dislocation between the scope of peripheral knowledge and the way in which that knowledge is valued by agents (peripheral and central). The postcolonial sense of this can be better understood through Funari's criticism from a sociopolitical perspective:

> Hodder can write about the 'contemporary West' (Hodder 1986: 167) only because there is a non-West, maintaining economically the so-called 'alternative' perspectives, (western) indigenous, (western) feminist, and (western) working-class archaeology. It is symptomatic that even though the concept of *West* is accepted somewhat unconsciously by *western* archaeologies, it imples (sic) the existence of Third World (or non-Western) archaeology. (Funari 1989: 65)

The dependence between central and peripheral archaeologies was framed within neocolonial relationships – both academic and economic – which featured as coloniality. Within coloniality certain knowledge and certain enunciators are underestimated in relation to a "more perfect" knowledge emanating from the central academies. Like Latin American postcolonialism that would spread a couple of decades later, Funari (1989) both established criticism of the geopolitics of knowledge as a boost to the emancipator action (decolonial, as it would be called later) and located the place of liberation to the outskirts of the West: "There are therefore two radical tasks for peripheral archaeologists. First, to oppose inner and outer oppression and second, to promote a *new past*, in order to liberate people in the *present*. In this context, peripheral archaeology can provide central archaeology with a very pertinent critique, by stating the limitations of western archaeology or, at least, its one-sidedness" (1989: 65).

A Meeting of Times

Towards the end of the 1990s, Cristóbal Gnecco's text "*Historical Multivocality. Towards a Postcolonial Cartography of Archaeology*" was published; it would become the primary reference in the introduction of the discipline to the postcolonial debate. Perhaps the most significant contribution of this work to the postcolonial debate resides in the sharpness with which Gnecco exposes the colonial sense, or better the *endocolonialism* of the scientific program of the archaeological discipline. He writes: "Archaeology is part of the cognitive apparatus of the West and one of the refined expressions of its temporary thought" and "Western time is a tool of political domination and the time that builds the archaeology is Western time, not the time of the others" as well as "These questions are no longer limited to reflections carried to the interior of the disciplinary practice, as happened during the years of formation and consolidation of the scientific archaeology, they involve the same status of the discipline in the context of other knowledges and within the framework of the social contexts of their production; they are related, in short, with what I will call political economy of archaeology. In this sense, the most important question we have to ask ourselves about the role of archaeology in a contemporary context, twice postmodern and unsubordinated" (Gnecco 1999: 17–18). Clearly, for Gnecco it is not just that archaeology should recognize the inheritances of colonialist past to get rid of them. Nor does he say that archaeology, only through recognizing in its history its colonialist origin, is able to deviate from those formerly unacknowledged negative features.

Gnecco's program is critical enough to expose the mechanisms through which archaeology is a part of the arsenal of Western knowledge to subordinate other knowledges. In this sense, the key concept that is introduced is the one of *endocolonialism* or *internal colonialism*. Despite the

many multicultural readings that it has suffered, Gnecco's program is not a multicultural program of recognition and respect for differences; on the contrary, what he calls a "multivocal meeting" is a field of political struggle in which archaeology can enter only honestly by renouncing its hegemonism and opening itself to self-transformation. It is not possible for archaeology (or the Western disciplining of time, in general) to recognize in a *locus* vis-à-vis other times, without abandoning, in the first place, the universalism which constitutes the behavior characteristic of Western time, and secondly the alocronism with which it subordinates other times. Gnecco's text meant, at the end of the 1990s, a programmatic statement much more than an already transited path. Signs of that can be read in his provocations to the openness, transformation, and relativism as well as in the optimism with which post-processualism was then characterized as "unsubordinated" knowing of Western hegemonic practices. Such attitudes are common in other texts of the 1990s commented on this entry.

Ruptures and Metaphysics

History-object is marked by the colonial experience, i.e., South American history occurs before and after the colonial experience; there is a precolonial history of autonomy and a colonial history of subjugation. The postcolonial perspective comes to state that the colonial experience did not perish nor was it diluted with independence. The colonial experience has constituted colonial history as *history* and precolonial history as *prehistory*, or as a period without history. Archaeology has come both to liberate the precolonial history of the colonial gaze that constitutes it as without history and to extend the colonial sense of history over non-colonial times.

The subject of history is also marked by the colonial experience, i.e., that both the history of what happened since the colonial experience as the history of what happened before the colony, i.e., postcolonial and precolonial histories (the latter on which archaeology claims exclusivity), are focused, studied, and narrated from post-colonial perspectives. The observations offered by archaeology about precolonial history are, inevitably, still a postcolonial gaze. This is because the subjectivities of both the historian and the precolonial archaeologist are constituted by the same colonial experience.

The *constituent* character of the colonial experience in relation to archaeology is indicated in its disciplinary demarcation. Additionally, it is also interesting to explore its *constitutive* character, that is, the way in which coloniality implicitly constitutes or shapes the facts of experience, and then the scientific understandings of history. To the first constituent relationship, called *direct*, a constitutive *recursive* relationship is added, "once the matrices that define and frame scientific disciplines are established, and are put into motion, the knowledge of objects is already mediated by this division of labor, although its origins are unnoticed, thus facilitating its reproduction with all the appearance of naturalness" (Haber 1999). Haber explored how coloniality acts upon archaeology, through the analysis of the theoretical-methodological model for the interpretation of the colonial archaeology of northwestern Argentina (called "Caspinchango model" following the fact that it was based on the classical interpretation of a so-called type-site, Haber 1999). The classic report on the Caspinchango site, written by one of the founders of the archaeological discipline, Salvador Debenedetti, thus became a canonical text for archaeology about the long war period between Calchaqui and Castile, designated as the Hispanic-indigenous period by archaeology. It enhanced indexes of subjection (Christian rosary glass beads) and decomposition (the decay of ceramic manufacturing). Classical excavations at Caspinchango, however, offered some notable stratigraphic sequences that could undermine the interpretation of an irreversible trend towards the West, something that was predicted and meticulously observed by Félix Outes (Haber 1999). Despite signs to the contrary of this critique, however, the Caspinchango model won monolithically in the archaeological discipline. The question is not simply about the facts but also about those deep, extrascientific, and immanent conditions for the creation of the facts of experience. If the interpretation of the history-object follows an interpretative canon beyond the facts,

it is because the conditions by which those facts are facts do not correspond exclusively to the materiality of things nor to the objectivity of the record but to a cultural assumption, an epistemic understanding of historical time as founded on a momentous event, a rupture or gap that, beyond facts, is, as a consequence, metaphysical.

Indigenous historical archaeology is therefore an impossible endeavor, a no-time that should be moved, either towards a prehistorical past or to a nonindigenous ethnic group (Criollo, Mestizo, Christian, etc.). Preterization of the indigenous (past and present) is necessary for the consolidation of a cultural collective that needs to expurgate its indigenous para-Christian, or non-Christian, and doubtfully Western content. The *metaphysical rupture* in which the colonial understanding of history is based becomes thus encoded within the disciplinary frames of archaeology, i.e., its demarcation of object and method. In this way, being an archaeologist, that is to say, exercising knowledge within the boundaries defined by the disciplinary framework, is exercising a knowledge founded in metaphysical rupture, in a cultural form that colonial difference adopts in history as written from the canon of the national state. But, if archaeology carries even inadvertently, in its most basic internal structure, coloniality, there is no other way for archaeology than to reproduce and expand those colonial conditions of knowledge.

Future Directions

An Uncertain Way Out

The postcolonial debate has some specific areas unique to South America. Long before postcolonial theory was spreading in global academy, various aspects of South American thought interrogated similar issues. The nineteenth-century essayists, and also many and diverse currents of thought in the early decades of the twentieth century – including the reconstruction of the Andean Marxism by Mariátegui, the "cannibalist" current in Brazil, Forja Group in Argentina, to name a few – were of great influence in South America. Dependency theory and development were theoretical elaborations that received strong impetus in the middle of the last century. The theology of liberation, magical realism literature, and social muralism are some currents that transformed critical positions from other areas and many times on a Latin American scale. These and many other thoughts, together with the experience of hundreds of social movements and indigenous and peasant movements, contribute to the fact that the reception of the postcolonial debate has not adopted the known form of the simple translation of texts from the English-speaking academy.

Many of the postcolonial thinkers were grouped into what is known as the Modernity/Coloniality Program, although this label leaves out hundreds of relevant intellectuals, among them the ones that were gathered by the Aymara Oral History Workshop. So, postcolonial South American theory, rather than aligning itself with any global intellectual current, is a particular space of thought and theoretical practice that dialogues with various intellectual currents (including postcolonial theory, structural history, and queer studies). Such a space is characterized by a theoretical interchange with social movements, indigenous peoples, and peasant organizations in an active anti-colonial struggle. It is within this experience that the postcolonial prospects in South American archaeology must be understood, as participating in these conversations rather than the simple application of a theoretical approach to the field. At the same time, based on the historical continental experience, South American perspectives within archaeology, as well as the rest of the fields, maintain a commitment beyond the deconstructive critical moment, in what has been called "the decolonial turn."

The involvement with indigenous movements has been one of the most visible experiences in the decolonial sense. Unlike the multiculturalists' positions, decolonial positions have attempted to move beyond the aim of respect for the rights to diversity and historic reparation, towards recognizing indigenous thought as real theoretical perspectives capable of establishing symmetry and even move the Western, disciplinary, and intellectual constructions, and not simply as objects of knowledge or a subject of law. What in other cases

has been defined in the context of the restitution of material culture to indigenous descendants is reconfigured in South America as an encounter between archaeologies aware of their positions in the postcolonial field (Gnecco and Hernández 2008). What in science is understood as a traditional culture from traditional, ethnoscientific, or *ethic* perspectives is configured as theories of relationality that cannot be known without an epistemic-political shift that involves an openness to move the broader cultural and disciplinary certainties (Haber 2009).

The involvement with social movements (peasants, anti-mega-mining, indigenous peoples) leading the anti-colonial struggle in rural areas where archaeology is usually practiced has led us to consider epistemic priorities and other values other than the traditional basic (truth-oriented) and applied (market- and development-oriented) science, such as life – or even a good life. In all of these developments, archaeology not only expands on innovative fields guided by the goal of helping each other but also enters into a theoretical and epistemic conversation which transforms it (Curtoni and Chaparro 2011; Jofre 2010).

Finally, it is necessary to mention the efforts that, even at an initial stage, apply to the formation of networks of research and debate that link academics and movements of various South American countries with other countries of the geopolitical South, seeking to configure locales of thought and practice that are not mediated by the central academy. A case in this regard is the establishment of the South-South Network on Cultural Heritage and Globalization and the formation of South America/South Africa networks.

This entry cannot be a history of postcolonial archaeology in South America without addressing the history of the colonial constitution of history, archaeology, and South America as colonial categories. But that a history of history (or better an archaeology of archaeology) is not a mere intellectual movement locked in the campuses from where it observes what is happening "out there." If any South American perspective on things really exists, it has to be one according to which the drama of the collective history passes through each molecule of thought. This is a case as demanding for the archaeological discipline as promising for those who think it is simply unbearable to abandon the anti-colonial yearnings. Decoloniality and indiscipline could be the key words of the history that is yet to be written.

South American Geography and Chronology

Vivian Scheinsohn
Instituto Nacional de Antropología y Pensamiento Latinoamericano-Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET)/Universidad de Buenos Aires, Facultad de Filosofía y Letras, Buenos Aires, CABA, Argentina

State of Knowledge and Current Debates

In the international archaeological literature, South American archaeology has been mainly interpreted by imposing Northern Hemisphere concepts and labels. Some years ago (Scheinsohn 2003), I have argued in favor of considering South American diversity and its particularities which runs counter to the application of concepts elaborated elsewhere. While decolonizing literature expands in English-speaking countries, most known English books on South America archaeology are still written (e.g., Moore 2014) or edited by non-South American archaeologists (e.g., Peregrine and Ember 2001). Even when different contributors are included, those from South American countries are in frank minority (e.g., Peregrine and Ember 2001, only 2 out of 19 contributors are South American). Thus, South American archaeology in English language publications is still portrayed in terms of extra-American archaeology without considering vast quantities of literature written in Spanish. The reasons are multiple: the overall Northern Hemisphere dominance in science (and hence in archaeology), the preference for an author that speaks from a known point of view, the underplaying of South American archaeologists, etc. This last reason is quite problematic given the early archaeological developments in different South American countries (i.e., Tello and his disciples in the first half of the 1900s in Peru Ameghino and Moreno and their disciples at the end of nineteenth century in Argentina, etc.) and its strong research traditions.

But something has begun to change. Some authors have acknowledged that Old World labels mask South American diversity (e.g., Dillehay 1999, 2008, among others). South American archaeologists have begun to publish more in English, thereby widening their impact. Also, one of the two editors of Latin American Antiquity (the SAA's journal for the region) has been Latin American from the start of the journal, in 1990. Part of this progress has been the result of deliberate efforts by northern hemisphere institutions to train Latin American archaeologists, especially the University of Pittsburgh which, since the late 1980s, has provided Heinz fellowships to grad students from throughout Latin America with most of the graduates have returned home. Also, although with local impact, it is remarkable for the existence of a series of internally financed, permanent projects. The main example came from Peru coast, north of Lima, with projects run and staffed by national archaeologists as in Sipán (since 1987), Huaca de la Luna (since 1990), and Caral (since 1994), some of them accompanied by informative site museums and spectacular exhibits. The development of cultural resource management projects in many countries of the region has also facilitated archaeologist to engage in regular jobs. Finally, South American archaeologists have begun to establish their own networks (e.g., Reunión de Teoría Arqueológica de América del Sur, TAAS; Encuentro Latinoamericano de ArqueoZoología, ELAZ; the Neotropical Zooarchaeology Working Group, NZWG of the International Council for Archaeozoology, ICAZ; etc.), overcoming the old

barriers set between South American archeologists and cutting down the dependence on Anglo-Saxon authors. These barriers are also related with one of the South America particularities: currently is divided in 12 independent countries (Argentina, Bolivia, Brazil, Chile, Colombia, Ecuador, Guyana, Paraguay, Peru, Surinam, Uruguay, and Venezuela) and French Guyana (overseas department of France, see Fig. 1). The majority of those countries are Spanish speaking with the exception of Brazil (Portuguese), Guyana (English), Surinam (Dutch), and French Guyana (French). This picture creates specific linguistic obstacles with the latter countries but also issues related with different national scientific research policies and circulation of information among the former that affected also archaeology. As Politis has signaled (2002), these divergences in their historical and sociopolitical contexts led to distinct regional and national archaeologies.

In any case, South America's distinctiveness has begun to be recognized. Among those features are the following: (1) it was the last continent colonized by humans (leaving Antarctica aside);

South American Geography and Chronology, Fig. 1 Map of South America. Shadowed areas represent different heights measured in meters above sea level

(2) it has the greatest latitudinal span among all the continents; (3) the North-to-South-oriented Cordillera de los Andes has far-reaching geographical and ecological effects, including a high altitudinal variation; (4) there were multiple animal and plant domestication locales; (5) as recent research allow to conclude, it has also a different model of population growth than other continents (Goldberg et al. 2016); and (6) it is also home to the developments of states and empires. In that last case, the problem is that the Andean phenomenon was so overwhelming that most of the South America readings were biased to it, to the detriment of focus on the diversity of cultural processes elsewhere in South America.

Since this entry is meant as an introduction to South American Archaeology for the international reader, most of the subjects are dealt with very briefly when there are specific entries on the same in this volume (see Cross References below). I will therefore only expand on certain issues that are less known or noteworthy and seek to deal mostly with archaeological literature available in Spanish. As an additional warning, I should add that, since I am an Argentinean archaeologist, most of the examples I will present are biased toward that country.

Geography

Four are the main characteristics of South America geography:

1. Continental shape: South America (Fig. 1) lies mainly in the Southern Hemisphere, stretching from 12° N to 55°S going from tropics to subpolar regions (Morello 1984). It has the approximate shape of an inverted isosceles triangle, with the narrow end pointing south. This narrowing begins south of the Equator and is more pronounced from the Tropic of Capricorn (23°S) onto the tip of the continent: in the middle latitudes of the continent, the longitudinal width is 15° and in the southern end just over 5°. This elongated shape implies an increasing marine influence to the South, moderating summer and winter extreme temperatures. This results in environments that are less harsh than expected by latitude alone and explains the lack of subpolar conditions, tundra, and permafrost in ice-free zones (Morello 1984).
2. The North-to-South-oriented Cordillera de los Andes (see darker area in Fig. 1) creates a Pacific coastline characterized by high relief, a narrow marine shelf bordering a deep trench, and short drainage basins with sharp vertical motions, as opposed to the Atlantic coastline, characterized by low relief, broad marine shelf, and extensive drainage basins and alluvial fans (Kellogg and Mohriak 2001 cit. in Barretto 2005). The Eastern part of the continent has outcrops of hard Precambrian rocks with a shallow cover of sedimentary rocks (Kellogg and Mohriak 2001 cit. in Barretto 2005, see intermediate darker area en Fig. 1). Most of South America's fluvial drainage flows out to the Caribbean or the Atlantic and away from the Andes, providing a world-class example of continent-scale drainage control by plate tectonics (Kellogg and Mohriak 2001 in Barreto 2005: 888). The high Andean mountain chain controls the circulation of humidity-bearing Pacific winds, creating patches of high ecological diversity (Morello 1984).
3. Three large river basins: Orinoco, Amazonas, and Paraná-Río de la Plata (Clapperton 1993, see Fig. 1).
4. A large arid and semiarid surface, the South American Arid Diagonal, going from the Equator to 54° S (Morello 1984).

Vegetation

Phytogeographically, we can define three main zones (Clapperton 1993):

1. East of Andes with tropical (Caatinga, Cerrado, transition forests and rainforests), subtropical (palm trees, parkland, and savanna, Pantanal in SW Brazil, see Fig. 1), and temperate vegetation (Pampas and Chaco grasslands and thorn forest, Patagonian steppe with dry resistant grasses and shrubs, see Fig. 1);
2. West of Andes (from North to South) with tropical rain forest, tropical desert (South Ecuador to Northern Chile), evergreen broadleaf forest (Central Chilean Valley), Valdivian

rain forest, deciduous forest, and Magellanic moorland in Southern Chile and Argentina.
3. Mountain vegetation with Páramo, Puna, Andean, and a subandean forest belt in the Southern Andes and Planalto (Brazilian Highlands with tropical and subtropical forest and grasslands see Fig. 1).

Paleoclimate

Given its high latitudinal position, South American Pleistocene continental glaciations occurred only in the Southern Andes (Clapperton 1993) and were milder and more restricted than in the Northern Hemisphere. Last Maximum Glacial (LGM) was reached at ca. 21,000 BP and the late glacial interval (LG) in the tropical Andes spans from the end of the LGM to 11,500 calendar years BP (Seltzer 2007). During LG there are several documented advances of glaciers, but their regional coherency has still to be determined. By the Early Holocene, glaciers had retreated to their modern limits in tropical Andes (Seltzer 2007). A thermally optimum climate is implied at most sites for the Middle Holocene centered around 8500–5500 BP, warmer and drier than at present (Clapperton 1993). As in the Northern Hemisphere, three Neoglacial advances have been modeled, but new research suggests additional events. Readvances were dated between 4700 and 4200 BP, 2700 and 2000 BP, and the last, corresponding to the Little Ice Age, between 1340 and ca. 1850 AD (see Clapperton 1993; Rabassa 2011). Some authors recognized the effects of the global warming event known as the Medieval Warm Epoch in South America and dated it between 1080 and 1250 AD (Villalba 1994; Fletcher and Moreno 2012; Bird et al. 2011). Also, after 5800 BP, with the return to Neoglacial conditions, El Niño Southern Oscillation (ENSO) was onset around 3200–2800 BP (Sandweiss et al. 2001).

Chronology

Peopling (c. 15,000–10,000 cal BP)

An intense debate exists regarding when and how South America was peopled. To date, linguistic, morphological, archaeological, and genetic evidence points to a pre-Clovis entry from Asia through the Bering land bridge, which connected Eastern Asia to North America during the last glaciation (Llamas et al. 2016). The Clovis first model, which posited Clovis people as the first settlers, has been questioned by the existence of pre-Clovis sites in South America as well as in North America (e.g., Paisley 5 Mile Point Caves, Schaefer and Hebior, Buttermilk Creek, Page-Ladson, etc.). But South American early sites are very different from what would be expected under the Paleo-Indian label (Scheinsohn 2003). Monte Verde II in Chile, the first fully accepted pre-Clovis site (sites still under scrutiny will be left aside for this review), has been dated at 14, 220 cal BP (or earlier see Dillehay et al. 2015) and presents a large number of artifacts, habitation structures, hearths, faunal remains, and plants (Dillehay et al. 2008) which clearly played an important role. In reference to this last resource, in the North of South America, some researchers support the idea that, during the Pleistocene, people created their own patches of resources in order to increase their effectiveness (Gnecco 2000; Politis 2002; Piperno and Stothert 2003). In any case, the importance of plants is recognized by the fact that ca. 10,000 BP intensive plant exploitation has begun in Central Andes and possibly in the eastern tropical lowlands (Dillehay 2008). Also, unlike North America, there are few South American sites with clear evidences of extinct megafauna exploitation (Dillehay 1999), and all those sites contain modern animal species which played a more important role. As Dillehay (1999) pointed out, as long as North American labels are applied, many South American Terminal Pleistocene sites present a diet more in line with an Archaic Period. In terms of the scant human skeletal evidence, they continue to point toward a relatively recent Asian origin (e.g., Schurr 2004; Pucciarelli et al. 2003). Genetic data suggest that early populations remained isolated for many generations in Beringia (in what it is called the Beringian Standstill model) or even in America, forming the basal Native American genetic lineages derived from Asian ancestors, which is in concordance with

paleoenvironmental evidence (Llamas et al. 2016). In any case, by 15,000 years ago (although this first entry could be extended to 25,000 years ago or more), humans began to settle North America and soon they entered to South America. Between 14,000 and 12,000 years ago, at the end of the last glacial advance, South American human populations were probably small and sparsely distributed (Dillehay 2008). They were mobile with large foraging territories (Dillehay 2008). These first foragers are well documented at Central Andes, Southern Patagonia, Pampas, Colombia, Perú, Chile, and eastern Brazil (Lavallée 2000; Dillehay 2000, 2008; Politis et al. 2016). But if first settlers migrated along the Pacific coast, some of the best evidence is probably underwater, along the former coastline, flooded by rising sea levels from the melting ice sheets. That effect would have been greatest in some regions of eastern South America, where the costal land is relatively flat and low lying, leading to drowning by postglacial eustatic sea level rise and thus hampering the discovery of sites of this age.

Maritime resources certainly played an important role at coastal Peru and Northern Chile during Late Pleistocene and Early Holocene transition since people at the Pacific coast were prepared to exploit the sea from the beginning (Dillehay 2008; Sandweiss and Richardson 2008). Another significant fact is that the most ancient rock art of South America, located in NW Argentina, North of Chile, Peru, and Brazil dates back to Late Pleistocene/Early Holocene transition (Tratebas et al. 2012).

Early Holocene (10,000–8,000 cal BP)

The onset of the Holocene saw a wide diversity of hunter-gatherer adaptations in South America. After 10,000 BP the archaeological signal becomes intense making it difficult to talk on a continental scale given the record richness (Scheinsohn 2003). Early sites have a wide variety of projectile points, which include such as El Jobo, Paiján, triangular, willow, and fishtail points (Gnecco 1990). Lanceolate El Jobo points show a limited distribution (Northern South America), but it should be added the lanceolate points recorded at Monte Verde, the Argentinean Northwest, and Northern Chile. In this case, although similar, convergence could be argued based on the generality of its design (Borrero 2001). *Cola de pescado* or fishtail (from the shape of the stem) points were widespread in Southern South America, between 11,600 and 10,200 BP, from Southern Patagonia to the Pampas and Central Chile. Since many present fluting, some have linked them with Clovis points, regardless of the differences in their morphology (Politis 1991) and reduction sequences suggesting separate origins (Nami 1996). Others researchers interpreted the dispersion of fishtail points as the result of functional effectiveness and a shared technology among different highly mobile populations, in which circulation of information played an important role (Aschero 2000). Projectile point typology apart, in Central and Southern Andes, Patagonia, Tierra del Fuego, and the Pampas, hunters relayed mostly in guanaco as a prey. The guanaco (*Lama guanicoe*) is one of the biggest herbivores in South America and was commonly available in various environments (Mengoni Goñalons 1999; Borrero 2001; Muñoz and Mondini 2008). Thus, in Pampas and Patagonia, after megafauna extinction, faunal diversity decreased, with an increase of guanaco exploitation.

Amazonian foragers are recorded in this moment (Roosvelt et al. 1996), in open contradiction with the traditional assertion that it was colonized later by groups dependent upon horticulture (see a critique of this position in Politis 2002). In the immediate lowlands and in the Central Andes, cultigens began to be recorded. Squashes are among the most ancient cultivates (around 10, 000 BP) at Las Vegas (Ecuador), San Isidro (Colombia), and Zaña Valley (Peru see Piperno 2011) followed by peanuts (*Arachis hypogaea*) and beans (*P. vulgaris*, *P. lunatus*). By 8800–7600 BP in the Zaña Valley (Peru), a significant number of dietary calories and nutrients came from crop plants (Piperno 2011). Early cultigens are also recorded in hunter-gatherer contexts (as in Huachichocana, in Northwestern Argentinean, Fernández Distel 1974).

Middle Holocene (8000–4000/3000 BP)

The increasing temperatures of Mid-Holocene had different effects in diverse areas. For instance,

in the Chilean Atacama Desert, a *silencio arqueológico* (archaeological silence) has been proposed (see Nuñez et al. 2002) for the period, meaning that between 8000 and 5500 BP, when aridity increased, a lack of human occupation is recorded. Some authors (e.g., Aschero 2000; Nuñez et al. 1999) maintain that this should not be attributed to the abandonment of the region but instead represent a retreat of human populations to strategic spots where resources were concentrated. Seasonal programming, transhumance with complementary use of resources in high and low areas, information flow through wide ranges, and symbolic systems followed (Aschero 2000; Nuñez et al. 2002). Eventually animal domestication started in the Andes between 6,000 and 4,000 years ago (Mengoni Goñalons 2008) with llamas and alpacas originating from guanaco and vicuña, respectively (Wheeler et al. 2006; Stahl 2008). Evidence suggests more than one simultaneous instances of domestication (in addition to the Peruvian central highlands).

At this time maritime coastal adaptations were also consolidating, and some of them would set the foundations for the later emergence of sedentarism (see below). Three main areas show these adaptations:

(a) Peru, Ecuador, and Northern Chile where marine hunter-gatherers were exploiting deep sea resources, at first with simple hooks made of shell and then with composite hooks, nets, and harpoons. The rich marine environment made fishes and mollusks available to humans living along the Pacific coast, which allowed the construction of villages and ceremonial centers during the climatic change that took place between 8000 and 5000 BP (Leon 2015). Literature suggests that these resources allowed the development of complexity in the Andean coast (Moseley 1975), as seen in the Complejo Chinchorro (Northern Chile, Arriaza 2003, see below) and Las Vegas and Nanchoc (Peru, Dillehay 2000).
(b) The Brazilian Atlantic Coast: *sambaquí* (shell mounds that proliferated from 6500 BP to 1000 BP) sites are conspicuous, and they could rise up to 30 m. These mounds were built by complex hunter-gatherers. Many were interpreted as burial structures, but others were semi- or permanently residential (De Blasis et al. 1998).
(c) Southern South America: According to Orquera and Piana (1999), specialized gatherers and fishers existed from 6000 BP at many sites of the Magellan and Fuegian channels (southern tip of Patagonia, etc.). Their main staples were pinnipeds. A main feature characteristic of this kind of adaptation was the abundance of bone tools (Scheinsohn 2010).

Also, occasional maritime faunal exploitation in the Middle Holocene has been argued for hunter-gatherers at the Southern Atlantic Pampean coast from the exceptional site of La Olla (Bayón and Politis 2014). Sporadically exposed in the intertidal zone of the present beach, it has been dated between 7,400 and 6,480 years BP. The site served as a place for the processing and consumption of pinnipeds and was accompanied by wood tools, which are exceptional in the region, as well as bone tools, stone tools, and bone and plant remains (Bayon and Politis 2014).

Apart of marine exploitation, terrestrial hunters, especially those living in the Andes and Patagonia, continued to focus on camelids, particularly, guanaco (*Lama guanicoe*). Coevolutionary relationships developed between humans and camelids, first as wild prey (see L'Heureux 2002) and eventually as domesticated (llama) in the Andean region (see below). Also, a great variety of new artifact designs emerged as plant-processing tools and bola stones, which were found in many grassland sites (Scheinsohn 2003).

Finally the emergence of complex mortuary behavior is recorded in the whole continent, in contrast with the scarcity of human burials in Late Pleistocene times. Climax was reached with artificial mummification in Complejo Chinchorro (Northern Chile), starting around 7000 BP. Individuals of all ages and genders were defleshed, butchered, eviscerated, dried, and then reconstructed, stuffed with animal and plant fibers, and body parts were modeled with clay forming a complex funerary bundle (Arriaza 2003) that were accompanied by abundant offerings such as

textiles, mats, and feather bundles. These funerary bundles are also recorded in Northern Argentina (e.g., Incacueva see Aguerre et al. 1973 and Huachichocana see Fernández Distel 1974) albeit without artificial mummification.

Late Holocene (4000/3000 BP to Present)

As from the Middle Holocene onward, humans in South America had acquired varying degrees of sedentarism, had developed complex hunter-gatherer societies, and had given way to a new lifestyle based on food production which, in some cases, leads to the development of chiefdoms and states (Scheinsohn 2003). South America was not solely a hunter-gatherer continent any longer: there were exchanges with different kinds of neighbors as well as oscillations between foraging and production, symbiosis, and dependence (Scheinsohn 2003).

In South America, as in other parts of the world, post-Pleistocene environmental changes were influential for the development of food production. For instance, the confluence of humans and animals at certain favorable points or ecorefugia (an idea probably related with Gordon Childe's model, see Childe 1928) during the arid interval, which caused the *silencio arqueológico* in certains spots of the Puna (Andean highlands), in others could lead to a logistic strategy, which in turn stimulated animal domestication, as was registered in Puripica 1 and other Northern Chile sites (Nuñez et al. 1999). However, environmental factors will not lead all human populations into food production necessarily.

In hunter-gatherer territories, increased density of sites and intensification of resources exploitation characterize this period (Scheinsohn 2003). In Patagonia, people were irregularly distributed (some sites are constantly reoccupied, e.g., Cerro de los Indios I, Figuerero Torres 2000) not only along rivers and lakes but also in lowlands, exploiting the highlands and forests. Few places remained empty. Also wide exchange networks are verified. For instance, obsidian sourcing of artifacts from hunter-gatherer contexts in Patagonia shows sourcing from 200 and exceptionally up to 800 km away (e.g., Stern et al. 2000). Also, in one burial site from Rawson (Patagonian Atlantic coast), dating back to the Spanish arrival in this area, a bronze ax similar to those produced in Northwestern Argentina was found, about 2000 km away of its origin (Gómez Otero and Dahinten 1997–1998). Networks and denser sites were evidencing social and cultural complexity (Dillehay 2000). One manifestation of this complexity was the presence of earthworks in Amazonia, Venezuela Llanos, Upper Magdalena River, Sierras de Tairona, and southern Cerritos (SE Brazil and E Uruguay) which allowed to postulate chiefdom emergence in some of these places (Politis 2002).

Food Production

Pearsall (2008) argues that plant domestication is a result of prolonged forager-plant interactions. There are three thresholds of domestication and agriculture in the Andes. At first, in the Early Holocene, there were frequent and dispersed plant domestications. Then, early domesticates spread, through social interactions among forager/horticulturalists. Cultivation in that context was small scale. Finally increasingly productive crops fueled population growth, which led to the spread of societies into dependence on agriculture and farming (Pearsall 2008). As mentioned above, cultigens were developed since Early Holocene/Middle Holocene, but by 4500 BP, they were widespread. Anyway, it is impossible to indicate in South America a single center or core area of agriculture. The origins of crops are spread from the northern parts to the southern parts of the continent, west and east of the Andes (Piperno 2011).

Probably camelid pastoralism developed to deal with the environmental unpredictability that characterized Andean highlands (Puna) starting from specialized hunting of wild camelids (see above) followed by a period of herding management 5,000–3,500 years ago and the introduction of domestic camelids as early as 4,500 years ago (Lavallée et al. 1986; Yacobaccio 2007; Marshall and Capriles 2015). Pastoralism was complemented with other strategies such as fishing, cultivating, and hunting. Wild camelids were always present, so hunting and production practices complemented each other (Yacobaccio et al. 1994). Llama domestication contributed meat and transport, while

alpacas provided fine wool. Anyway it is important to take into account that it is quite difficult for zooarchaeologists to sort wild from domestic camelids given the size overlap (Stahl 2008).

In addition to these two camelids, the domesticated animals of South America include only one large bird (Muscovy duck, *Cairina moschata*, although it is unclear if it was domesticated in Mexico or South America) and a medium-sized rodent, the guinea pig (*Cavia porcellus*, Stahl 2008).

Central Andes Complexity

In South America, food production (agriculture, camelid domestication) and marine resources allowed the development of sedentism and hence of more complex entities. In Andes, three moments of fusion of many regional cultures (called the pan-Andean Horizons) alternated with moments of dispersion (Leon 2015, among others).

Some 3,500 years ago, Chavín de Huantar site, in the Central Highlands of Perú, was established as the center of the first pan-Andean Horizon, influencing sites more than 500 km away from it (Leon 2015). Around the beginning of the CE, Chavín's dominance dwindles and a series of regional cultures, both on the coast and highlands, developed. These cultures (Vicus, Mochica, Nasca, Recuay) achieved great expertise in pottery, textiles, and metallurgy (Leon 2015). A new horizon the Middle Horizon, or Huari/Wari, developed between CE 600 and 1000 which has interacted with Tiahuanaco/Tiawanaku in Bolivia (so it is called Tiawanaku-Wari Horizon, 400–1000 AD). They developed a complex road system and constructed cities with administrative centers, public buildings, fortifications, temples, etc. Llama caravans allowed a huge goods exchange in the Andes. This period was followed by another fission time with Chimú ruling the Northern Coast of Peru and Huanca ruling in Central Peru (Leon 2015).

The third pan-Andean Horizon was generated by the expansion of the Inca State (1470–1536 AD). The origins of the Inca date back to at least the fourteenth century CE. The Incas and a few of their neighbors focused on surplus production, constructing new irrigation canals and agricultural terraces to cultivate maize and other crops. Inca society eventually grew to be larger and more hierarchical than its neighbors, and its leaders began to establish ties to groups across the Cuzco region, relationships turning the city of Cuzco into a ceremonial center (Leon 2015). Spreading out from Cuzco, their empire extended along the Cordillera de los Andes from present-day Colombia to Middle Chile and Argentina. They conquered peoples by force but also establishing alliances. In any case, Incas profited economically and consolidated as Andean heritage, what John Murra's model has called the "vertical control of different ecological floors" (Murra 1972). The model demonstrates that the Andean ideal of self-sufficiency limited commercial exchanges, which were replaced by obtaining the different resources that each natural environment allowed to exploit. It was an internal exchange within the community, governed by the practices of reciprocity among their members and of redistribution between the chief or curaca and their subjects. Although the model has undergone variations, it is considered a reference for understanding Andean populations. Also, for the reconstruction of Andean history, it is important to mention the work of many Peruvian etnohistorians as Rostworowski (1988) or Millones (1987).

European Conquest

The study of arrival of Europeans in the Americas has been covered archaeologically by the development of historical archaeology (Paterson 2015). Churches, convents, and monasteries have probably been excavated more than any other type of site (Van Buren 2015). Other aspects researched have been early urbanism, frontier expansion, the organization of extractive industries, dietary change, the reconfiguration of rural landscapes, and the local implementation of Spanish colonial policy. More recently the organization of silver mining, the reconfiguration of rural landscapes, the impact of Western goods on indigenous practices, and the interaction with haciendas or large agricultural estates and catholic missions were studied (Van Buren 2015).

Crosby (2003) described the exchange of diseases, ideas, food crops, and populations between the New World and the Old World, following the

voyage to the Americas by Christopher Columbus in 1492, as "The Columbian Exchange." The Old World gained new supplies of metals, new staple crops (such as potatoes, sweet potatoes, maize), and other vegetables (as tomatoes, chili peppers, cacao, peanuts, pineapples, tobacco, etc.). The exchange also produced losses. European contact enabled the transmission of diseases (as smallpox, measles, typhus, and cholera) to previously isolated American communities, which caused devastation. On their return home, European brought syphilis. The effects of the Columbian Exchange were not limited to the parts of the world directly participating in the exchange (Europe and the Americas). It also had large impacts on Africa and Asia. For instance, the cultivation of crops in the Americas, along with the devastation of native populations from disease, resulted in a demand for labor that was met with African population's slavery, during the sixteenth to nineteenth centuries (Nunn and Quian 2010).

European expansion, especially from sixteenth century on, affected South America differently, depending on resources available and the socioeconomic complexity achieved in the different regions. For instance, as a new way to interpret Spanish conquest in the Central Andes, Lamana (2008), based on the study of written documents, considered that during the period between 1530 and 1550, Spanish domination did not manage to exert an effective control on the peoples conquered. Social actors measured their respective forces not only in the military field but in the symbolic one, which produced a mutual exchange of knowledge and learning while exploiting the advantages and weaknesses of the other. He considered that Inca agency was as important as the Spanish agency concluding that it was not a situation of complete asymmetry but of competing regimes of visibility and feasibility (Lamana 2008). For the specific case of Northwestern Argentina, Quiroga (2010) explored how colonial power was felt by the aboriginal population in Catamarca, Argentina, departing from written documents but also from archaeological evidence. Although the establishment of a colonial order exerted physical violence, the conflict over the power of representation was not minor, given that colonial rule had to construct, justify, and reproduce asymmetries. Struggles to generate and reproduce a colonial society put into play practices, actors, representations, and categories built also from the material culture. From this standpoint Quiroga (2010) reconstructed the role of the highlands since they were important in Andean economy because key resources were located there, but for the Spanish rulers, highland exploitation could acquire the meaning of questioning the local colonial power. The native people's ascent to the hills and the refusal to "go down" to the valleys to comply with the services demanded by the *encomenderos* at the beginning of the agricultural cycle was interpreted as an unequivocal form of resistance to the dominion (Quiroga 2010). She studied archaeologically the material consequences of this behavior.

As this occurred in the Central Andes, in hunter-gatherers territories, before direct domination occurred, European presence was felt as a scarcity of traditional prey (as in the southern tip of South America owing to European whaling and pinniped overexploitation, see Orquera and Piana 1999) and the appearance of new prey (European cattle). For instance, Spanish settlers in the Pampas did not thrive at the beginning of their colonization (sixteenth century), given their hostile relationship with local communities, and they returned home, abandoning their cattle to become *cimarrón* (wild). By the end of that century, wild cattle became so widespread that native populations, and later new Spanish settlers, adopted them as their main staple, hunting them intensively in what were called *vaquerías* (Scheinsohn 2003). Between the eighteenth and nineteenth centuries, when this wild cattle population began to dwindle, native populations took their prey from the estancias (ranches) by means of *malones* (Indian raids). They traded in what is now Chile, to acquire new products. The archaeological signal of this trade circuit was found by Goñi (1986–1987) in Malleo River Valley (Neuquén Province, Northern Patagonia, Argentina). Among the European cattle, which were quickly incorporated by native populations, the horse was critical. What North American

anthropologists called "horse complex" also appeared in South America, owing to the introduction of European habits related to the horse, coupled with the development of horse-related new inventions (Scheinsohn 2003). Because horses require special care (e.g., constant access to grasslands and water), according to Goñi, human population home ranges increased, in what Binford has called extensification (Binford 2001), meaning an intense use of wide home ranges out from more permanent settlements. Thus, while home ranges were widening, a certain degree of sedentarism was developing (Goñi 2000).

After independence from Spain, at the beginning of the nineteenth century, when South American national states conformed, the picture did not change very much for the South American Indians. In the second half of the nineteenth century, the now consolidated States extended their control over their national territories and sought to define international borders. In many cases this meant taking control of indigenous territories. Forceful methods were deployed and an escalation of violence ensued. As an extreme case, Argentine national government launched the *Conquista del Desierto* in a 1879 military campaign that set out to dispose Indian territory in Patagonia and turn the "desert" into "productive" lands by the hard work of the "civilized" white colonists. This plan led to what can now be termed a genocide (Delrío et al. 2010) of the indigenous communities in Patagonia and was carried out in three stages (Pérez 2016): (1) the discursive "manufacture" of the internal "other" that portrayed Indians as a "savage" and materialized in Indian deportations and/or distributions as rural or domestic workers in any part of the country where needed, in slave-like conditions; (2) a stage that could be now considered as state terrorism, materialized in concentration camps for Indians (as in Valcheta, Rio Negro), constant persecutions, and land dispossession; and (3) a final stage of silencing and invisibilization of the Indians (for the invisibilization concept see also Lazzari 2003, among others). The process of invisibility was so strong that even the notion of *mestizaje*, so central to other national discourses in South America such as in Peru and Brazil (Ramos 1998; De la Cadena 2000), was absent in Argentina (Quijada 2004). Along this process, the Argentinean state oscillated between to fix the Indians to a certain territory, in order to control them (as in farm colonies) and deterritorialization. The lands taken to the Indians were given to few powerful landowners and large commercial enterprises. Indians that survived the genocide were converted into proletarians or persecuted as well as invisibilized.

Contemporary Past

Scholars have researched also a variety of sites dating to the nineteenth and twentieth century which allowed to approach the most recent past from an archaeological point of view (e.g., Buchli and Gavin 2001). Among the most productive fields it should be mentioned:

1. Subacuatic archaeology, which emerged as a specialty in the mid-1990s, somewhat later than in other parts of the world, mainly in Brazil, Argentina, Chile, Colombia, and Uruguay (Elkin 2011), but with a high level of productivity and quality. As present, there remain vast areas of South America lacking underwater research and/or with an underdeveloped field of conservation of waterlogged materials (Elkin 2011).
2. Urban and industrial capitalism archaeology: as urban archaeology is widely developed, industrial archaeology has less examples, such as Therrien's (2007 cit. in Van Buren 2015) research on a nineteenth-century Colombian ceramic factory that was established shortly after the national independence and Vilches (2011 cit. in Van Buren 2015) study of the nitrate mining town of Chacabuco (Chile) which was abandoned in 1938 only to be reoccupied as an internment camp during Pinochet's dictatorship.
3. Battlefield archaeology as well as the study of military fortifications (related with Indian conflicts in Pampa and Patagonia, see above Goñi and Madrid 1996, and/or colonial and national forces conflicts, see Albuquerque 1995 and Ramos et al. 2011 both cit. in Landa 2013) is

another field which, recently, has been strongly developed.

4. Forensic archaeology and anthropology: although initiated in Argentina, related with its special circumstances, forensic anthropology and archaeology soon were developed in other parts of South America and Latin America. The fall of the Argentine military dictatorship (1976–1983) and the advent of a democratic government opened the way to investigate what had happened to the victims of enforced disappearance during the military regime. The Argentinean dictatorship has implemented a system to persecute their political opponents and make them "disappear." This included kidnappings, setting up clandestine detention centers, torture, and finally murder. Many bodies of those murdered were buried without identification as "NN" (no name, equivalent to unknown or the American John/Jane Doe) either in individual or in mass graves all over the country (Fondebrider and Scheinsohn 2015). When the democratic government started the investigation of these crimes, the lack of personnel trained in recovering skeletal remains at the forensic departments caused a major catastrophe: remains were only partially recovered, the bones suffered postmortem damage, and relevant associated objects such as bullets were not retrieved or even discarded. The Abuelas de Plaza de Mayo (Grandmothers of the Plaza de Mayo), an organization made up of relatives of victims who disappeared during the dictatorship, started asking for help to solve the issue. They contacted the Association for the Advancement of Science (AAAS) in 1984 which sent a delegation of forensic scientists to Argentina to attempt the recovery of their grandchildren kidnapped and to implement an exhumation method which prevented the destruction of evidence (Fondebrider and Scheinsohn 2015). This later mission was the duty of the American forensic anthropologist Dr. Clyde C. Snow, member of the delegation. While in Argentina, Dr. Snow asked for help with a first exhumation to professional associations, but possibly afraid of the uncertain political context, they were rather reluctant. So Dr. Snow resorted to undergraduate anthropology students from the National University of Buenos Aires and the National University of La Plata. The first exhumation using archaeological techniques was carried out in an individual grave located at the Boulogne cemetery, province of Buenos Aires, in June 1984. The group of students who participated in this first exhumation became the core of what would be the Equipo Argentino de Antropología Forense (EAAF – Argentinean Forensic Anthropology Team). Since 1986, the original team of medicine, archaeology, and anthropology students has grown and currently comprises 60 persons, specialist of many different disciplines. The Argentine experience was taken to Chile, Guatemala, Peru, and Uruguay where groups of young archaeologist and anthropologists had decided to create independent organizations. Colombia, Venezuela, and México already had anthropologists working for the state (Fondebrider and Scheinsohn 2015). In 2003, these regional developments converged with the creation of the Asociación de Antropología Forense de América Latina – ALAF (Latin American Forensic Anthropology Association) which, since 2004, has organized an annual international congress in a Latin American country and implemented a certification program. Also forensic archaeology related with the excavation and reconstruction of local clandestine detention centers during the military dictatorship as in Pozo de Vargas (Tucumán Province, Argentina) Club Atlético (Buenos Aires City, Argentina) and Mansión Seré (outskirts of Buenos Aires city, Argentina). Some of these facilities, usually abandoned after being under police or military control, apart from been judicialized began to serve as sites for memory and reflection. A survey conducted by Salerno et al. (2012) identified more than 20 archaeological interventions in former clandestine prisons in Argentina. Archaeological interventions in former clandestine detention centers were also recorded in Chile and Uruguay.

5. Applied archaeology or studies where the past helps in the understanding and planning of the present. In South America, zooarchaeology is a well-developed line of archaeological research. But Ramos Roca's (2014) work in the Caribbean region of Colombia is an example of the study of the cultural manifestations related to the consumption of wild animals and how this can have an impact on their conservation. Consumption of certain "amphibian" species, understood as those species that move between land and water and not as a taxonomical category, are the same that are recorded in archaeological sites revealing 3,000 years of use. Based on the study of written sources, zooarchaeological analyses and ethnological work with the indigenous communities, recovering information about traditional foods associated with the use of wild animals (patterns of consumption, preparation techniques, etc.), Ramos Roca (2014) established that any proposal for sustainable use and its conservation must seek to respond, in a harmonious way, both the need to recover viable populations of wild species and the deep-rooted tradition of consumption of those animals during Holy Week. For instance, defining hunting quotas, which additionally could include a minimum allowable size for the capture and sale of individuals, would be more effective than ban the species' hunting.

Final Words

Important theoretical works and astounding research projects are being implemented. Diversity is a key word to understand South American archaeology. This far from complete summary has unfairly left out many regions and fields of research. But while much was done, much remains to be done. For instance, it is necessary that South American archaeologist begins to speak the same "language" among them and overcome the barriers that the existence of different countries had established among us. Those barriers, although bluntly real in the present, made no sense studying in the past.

Funding is needed for research, but also it is necessary that research results were available and consulted by policy-making institutions. It is necessary that these institutions understand the importance of archaeology for defining policies for heritage management but also for historical and contemporary issues, especially those related with Native South Americans. And related with this last but not the least issue, Indigenous rights should be mentioned. As said above, the dispossession of Indigenous communities implied the land but also their cultural heritage. As the Endere's (2014) recent review stated, at the beginning of the twentieth century, several South American countries have passed archaeological heritage laws in order to set up the public domain over archaeological sites. In the second half of that same century, international legislation favored the process of indigenous rights recognition, since most South American countries subscribed to them. Endere (2014) posited that the onset of democratic governments in the region in the 1980s shaped a new political setting for indigenous people's claims. Hence, over the past decade, indigenous people's rights are increasingly being incorporated into legal systems. Most of South American constitutions (Argentina, Bolivia, Brazil, Colombia, Ecuador, Paraguay, Peru, and Venezuela) made a wide recognition of indigenous rights. However, indigenous cultural heritage continues to be ruled by specific archaeological heritage laws that do not include the participation of these peoples in their management. However focused on land claims and their well-being, indigenous peoples have recently increased their claims on heritage issues, particularly in restitution of human remains held by museums. The first two restitutions carried out in Argentina – the Tehuelche Chief Inakayal in 1994 and the Rankulche Chief Mariano Rosas in 2001 – were ordered by special laws, since their remains were legally considered public domain of the nation-state (although after that Argentina passed a general law that recognizes the right of communities to claim the repatriation of human remains held in museums, Endere 2014). Also Uruguay

obtained the repatriation of the Charrúa Chief Vaimaca Pirú from the Musée de l'Homme of Paris, France, and in Chile, demands concerning indigenous human remains have also been raised by Atacameño, Mapuche, and Easter Island peoples. In parallel, Argentina have been voluntarily restituted human remains to indigenous communities of other countries: the Ethnographic Museum Juan B Ambrosetti of the University of Buenos Aires returned a preserved Maori tattooed head to Te Papa Museum in 2004, and the La Plata Museum handed in the remains of two individuals to the Aché community of Paraguay in 2010 (Endere 2014). Also South American countries repatriated archaeological artifacts to other South American countries as was the unprecedented case, given the quantity of materials implied, returned to Perú, Bolivia, Ecuador, and México by the Argentinean Instituto Nacional de Antropología y Pensamiento Latinoamericano (INAPL). In this context, as Endere (2014) pointed out, the update of most cultural heritage laws and policies, the construction of dialogue, and the development of a collaborative archaeology with indigenous communities are the major challenges.

In terms of heritage protection, although some South American countries have developed tools for it, corruption and capitalism are still sources of conflict. Sometimes, the state is the first in infringe heritage laws, doing earthworks without previous archaeological impact studies. In Buenos Aires city, one of the biggest cities of the world, ancient buildings are tore down every day due to real estate speculation infringing the regulations. For constructors, paying fines is cheaper than complying with the law. And there is no hint of interest of the local and national government to endorse the compliance with the law. Heritage is used and abused by tourism companies everywhere (e.g., Macchu Pichu). Archaeologists, architects, and museologists are not considered necessary for these developments. The inevitable result will be the damage and eventually the disappearance of that heritage. The most flagrant example, in a continental scale, is the destruction provoked by Dakar Rally.

South American Rock Art

María Mercedes Podestá[1] and Matthias Strecker[2]
[1]INAPL, Buenos Aires, Argentina
[2]SIARB, La Paz, Bolivia

Introduction

South American and the Caribbean islands rock art has been produced in practically all known archaeological periods and up to our times. This entry deals with the following:

- The different kind of rock art of this subcontinent: rock engravings, rock paintings, and geoglyphs
- The distribution of rock art throughout South America, found in a great variety of geographic and cultural zones in nearly all regions from North to South and East to West including the Andean highlands and the lowlands of the Atlantic coast
- The history of research from the first reports on rock art till scientific studies as part of current archaeological and anthropological research
- References to the principal regional rock art surveys
- A summary of rock art chronology, from the first manifestations up to those produced in recent times
- Some aspects of rock art interpretation of the art
- References to rock art documentation and analysis, conservation, public and private administration of sites, as well as education campaigns in which local communities are concerned (Fig. 1).

Definition

The subject of this study is rock art in South America, including the Caribbean islands: rock engravings (petroglyphs), rock paintings (sometimes called pictographs), and geoglyphs.

South American Rock Art, Fig. 1 Rock painting from Cerro de las Cuevas Pintadas. Guachipas. Argentina. (Photo: INAPL Archive)

These categories of rock art are distinguished by their mode of production. Petroglyphs or engravings are motifs executed on a rock surface. Could be pecked, incised or abraded. Rock paintings are motifs painted or sprayed with a liquid mixture on the rock surface. Other rock art representations could be executed by a sort of crayon such as charcoal. There are some motifs which present the combination of both techniques: engraving and painting. Geoglyphs are large motifs produced on the ground, usually in desert regions, by arranging clasts (positive geoglyph, stone arrangement) or by removing patinated clasts to expose unpatinated ground (negative geoglyph). Mobile art is another important artistic manifestation which may be related to rock art; it consists of engravings or paintings executed on small objects, such as natural stones (Fig. 2). Grinding basins and cupules are, in many cases, associated to rock art.

South American and Caribbean rock art has been produced on rock walls of caves and rockshelters, as well as boulders and other rock surfaces of open-air sites, in practically all known archaeological periods, and up to our times. Deep caves with rock art in dark areas that need artificial lighting occur only in the Caribbean region. Rock art is found in all countries and in a great variety of geographic and cultural zones (with the exception of certain regions, generally lowlands) which lack

South American Rock Art, Fig. 2 Petroglyphs at Iaguy Guasu (Cerro Guazú/Jasuka Venda, Dept. of Amambay), Paraguay. Museo de Altamira

suitable rock surfaces such as the coastal region *Litoral* of Argentina.

Historical Background

South American rock art was noted in colonial times (from CE sixteenth to nineteenth century) by missionaries and numerous travelers (Greer 2001: 678). In the early Republican period (CE nineteenth century), travelers, explorers, and ethnographers contributed a wealth of information though in many cases with faulty recording and little care to detail.

Scientific interest in South American rock art began towards the end of the CE nineteenth century. In Argentina, F. Ameghino, J. B. Ambrosetti, and A. Quiroga published their findings between 1870 and 1890; in Uruguay, J. H. Figueira presented reports in the 1890s; and in Colombia, after first recordings by L. M. Girón (1892) and V. Restrepo (1895), systematic rock art research was started by M. Triana in 1922 though he – like many others – considered rock art motifs as a sort of hieroglyphs. In Bolivia, E. Nördenskiöld recorded a few rock art sites partially in 1904–1905 and 1913–1914.

Koch-Grünberg's pioneering work "Südamerikanische Felszeichnungen" (Berlin 1907, published in Portuguese 2010) is one of the first which may be considered scientific. He provided a synthesis and critical review of the state of knowledge of the art and a summary of sites he had registered during his ethnographic studies on the Brazil-Columbian border (1903–1905).

There is a notable increase in scientific work on South American rock art from the mid-1900s to present. Studies became more detailed and attempted to place the art into archaeological, ethnographic, and interpretive contexts.

In the late 1980s Colonial and Republican rock art began being studied in a combination of rock art recordings with ethnohistoric studies. For example, in Colombia, F. Urbina R. 2004; in Peru, R. Hostnig (2004); in Brazil, C. M. Guimarães (1992) (with regard to rock drawings by fugitive Negro slaves); in Bolivia, R. Querejazu Lewis (1992) and F. Taboada (1992); in northern Chile, F. Gallardo et al. (1990, 1999); and in Argentina, A. Fernández Distel (1992).

Key Issues/Current Debates

Main Geographical Areas

Regarding the cultural configuration based on traditions linked to archaeological cultures, historic information, and ethno-linguistic distributions, the following areas may be established:

- *Caribbean islands*: west India or the Antilles, in which two areas are defined as Greater Antilles (Puerto Rico, Dominican Republic, Cuba, Haiti, and Jamaica) and Lesser Antilles.

- *Lowland South America* as defined by Greer (2001: 665): the northern Amazonas-Guianas region of southern Venezuela, southeastern Colombia, southern Brazil, Guyana, Suriname, and French Guiana, as well as lowland regions of Ecuador, Peru, and Bolivia.
- *Central Brazil and northeast Brazil* as defined by Prous (1994: 89-124).
- *Southeastern coastal Brazil* as defined by Prous (1992: 511-513) comprises of areas attributed to the "Meridional Tradition" and "Coastal Tradition" (Prous 1994: 81–85).
- *The Basin of La Plata River* includes its principal tributaries and adjacent areas in Uruguay, Paraguay, south Brazil, and Northeast Argentina, with five subareas – (1) northern, (2) Atlantic, (3) lap of the Meridional Plateau, (4) southern, and (5) Chaco-Litoral (Consens 1995).
- *Andean South America*: divided in northern, central, and southern Andes, comprising the Pacific coast and highlands of Colombia, Ecuador, Peru, Bolivia, Chile, and northwestern Argentina, excluding southern Chile and Argentina.
- *West-central and central Sierras* in Argentina.
- *Pampa-Patagonia*: southern Argentina and Chile, extends to the top end of the continent and includes Patagonian Andes.

Regional Synthesis

Regional overviews have been presented from broad-areal, regional, country, and local perspectives (Greer 2001: 681). C. N. Dubelaar's Ph.D. thesis (1986) provided a synthesis of engravings on the South American continent and the Caribbean islands, detailing history of research, techniques of production, site characteristics, approaches to dating and interpretation, geographical distribution and classification according to "pilot motifs," and a comparison between petroglyphs of the Antilles and those of northeast South America. In later studies, Dubelaar presented inventories of rock art in the Guianas and adjacent areas, the Lesser Antilles, the Virgin Islands and Trinidad, as well as Puerto Rico.

Notable synthesis were provided for all areas and countries: *Caribbean area*: M. Hayward et al. (2009); *Venezuela*: R. de Valencia and J. Sujo Volsky (1987), J. Greer (1994, 1995, 2001), and F. Scaramelli and K. Tarble (2008, 2010); *Colombia*: G. Muñoz C. (1999) and A. Botiva C. (2000); *Ecuador*: G. González O. (2008); *Brazil*: N. Guidon (1991) on Piaui rock art, A. M. Pessis (2003) on Serra da Capivara rock art, A. Prous (1992, 1994), J. Marcos, A. Prous, and L. Ribeiro on rock engravings of southern Brazil and rock art of Central, Amazonian, and northeast Brazil (2007), G. Martin (1996) on northeast Brazil, and E. Pereira (2003, 2010) on the Central Amazonian *Peru*: J. Guffroy (1999, 2007) and R. Hostnig (2003); *Bolivia*: M. Strecker (1987); *Paraguay*: J. Lasheras et al. (2011); *Chile*: G. Mostny and H. Niemeyer (1983), Berenguer (1999, 2004), Núñez A. (1976) on rock art of Atacama, L. Briones (2008) on geoglyphs of northern Chile, and Troncoso (2008) on Aconcagua river, central Chile; *Argentina*: A. R. González (1977), J. Schobinger and C. J. Gradin (1985), Aschero (1999) on northwest Puna rock art, M. M. Podestá et al. (2005a) on northwestern rock art, M. M. Podestá et al. (2005b) on Patagonia rock art, and A. Recalde and E. Berberián (2005) on central Argentina rock art; *Uruguay*: M. Consens (1995), L. Cabrera Pérez (2008), and A. M. Florines (2004). A general view of *South American* rock art is presented by J. Schobinger (1997) and J. Schobinger and M. Strecker (2001). The Thematic Study edited by ICOMOS (2006) presents overviews on rock art in several regions of South America.

Chronology

In some of the South American countries – particularly in those with a long tradition of archaeological research – chronological sequences have been established on rock art which make it possible to assign the beginning of its production to the earliest occupations of hunter-gatherers which in the Northeast and Patagonian region of Argentina go back more than 10,000 years before present. In northern Chile and central-south Peru, somewhat later dates have been proposed for early rock art. Some regions in Brazil (Amazonia, Mato Grosso, Minas Gerais, Piauí, Peruaçu valley) have produced early dates for rock art (12,000–9,000 BP)

(Prous 2012). Guidon (2007) has proposed an extremely ancient rock art tradition for northeast Brazil (Serra da Capivara, Piauí) of some 48,000 years ago, while in the Amazonian region of Columbia (Serranía de Chiribiquete), rock paintings are believed to have started some 19,500 years ago; however, the considerable antiquity of these representations in Brazil is not accepted by a large part of the archaeologists and at present does not agree with the standard vision of early peopling of South America.

In the case of southern Peru, Toquepala y Sumbay caves have been related to human occupations dated between 11,198 and 10,413 AP and c. 7,300 AP and c. 6,300 AP, respectively (Muelle 1969 and Neira 1968) (Fig. 3). Some recent research by Guffroy (2007) and Hostnig (in preparation) have shed light on a natural style of archaic paintings with large representations of camelid figures accompanied by small stylized human figures. Most of these sites are located at an altitude of more than 4,000 m above sea level.

In most cases defining a sequence and antiquity of rock art styles is based on stylistic changes between motifs belonging to different superimposed layers and the correlation of the production and use of rock art figures with dated layers excavated at the foot of the rock art panels or in their immediate vicinity obtaining an indirect (estimated) chronology for the art. Frequently stylistic considerations play an important role, based on stylistic or iconographic similarities between rock art and other artistic productions.

On the other hand, there are very few "direct" or absolute dates for rock art which either provide a date for the rock art itself, for the rock surface underlying the art, or accretions overlying it. Dating should always be consistent with other archaeological data to be considered reliable. The first AMS dates (radiocarbon dating using accelerator mass spectrometry) of rock paintings have been reported for Argentina: – La Candelaria, Catamarca (Hedges et al. 1998) and Abrigo de los Emplumados or Media Agua 1, Jujuy (Hernández Llosas et al. 1999) – and Brazil: (Toca do Serrote da Bastiana, Piauí).

Rock art representations are present in all moments of human occupation of the South American mainland (preceramic hunter-gatherers, later phases of domestication, and early farmers/ceramists). Among the most ancient figures are non-iconic (abstract) designs, while in other sites figurative scenes occur including the representation of hunting wild animals, above all camelids (such as in southern Peru, northern Chile, Bolivia, northwestern Argentina, and Patagonia). In more recent periods, domesticated camelids are represented in pastoral scenes or in caravans that transported goods.

South American Rock Art, Fig. 4 Colonial rock paintings at Carabaya, Dept. of Puno, Peru. (Photo by Nicolas Merma)

After the European conquest and initial colonization (CE fifteenth to sixteenth centuries), the indigenous communities continued its production up to the late Colonial and in some cases even to Republican times. Colonial and historical rock art is characterized by the representation of horseriders and other anthropomorphic figures with European garments, Christian crosses, horses, etc. An exceptional site in the highlands of Bolivia features numerous scenes of folkloric dances. Battle scenes have been found in sites around Titicaca Lake, possibly related to the indigenous uprisings of the late eighteenth century (Fig. 4). Among recent petroglyph motifs are the representations of cattle marks which date from the mid-twentieth century (Podestá et al. 2005a). In north Colombia similar engravings in territory of the Wayuu Indians are interpreted as totemic emblems (Delgado 2010).

In some cases, rock art sites in the Andean highlands continue to be the focus of religious rites, as recent indigenous offerings and ceremonies demonstrate.

Interpretation

Interpretation of rock art sites should be the result of long-term interdisciplinary research taking into account many factors concerning the cultural framework of the art, its distribution and natural setting, associations with the regional settlement pattern in the specific time periods, as well as indications regarding the ritual, social, and economic uses of the sites.

In South America, the theory of shamanism and its relation to rock art has been scarcely brought up, with the exception of some researchers such as J. Schobinger (2010). More widely accepted is the idea that rock art served as a communication system in which petroglyphs, rock paintings, and geoglyphs are interpreted as markings along traditional routes of travelers and llama caravans passing through wide regions of the Andes. Numerous researchers have favored this theory, for example, L. Núñez A. (1976) with regard to the Atacama Desert and C. A. Aschero with regard to the Argentinian puna and northern Chile. The same interpretation has been applied to historical rock art of mid-twentieth century related to cattle herders that crossed the Argentinian-Chilean border (Podestá et al. 2005a). Petroglyphs in another region and ecozone, along Río Negro river in the tropical lowlands of Brazil and Colombia, are now interpreted as territorial markers and symbols-related mythical migration routes.

Interpretation of some rock art sites in northern Chile is based on ancient indigenous myths and ceremonies related to the agricultural cycle and the growth of llama herds.

South American Rock Art, Fig. 5 Rock paintings at Toca do Boqueirao da Pedra Furada, Serra da Capivara, Piauí, Brazil. (Photo by Alice Tratebas)

With regard to the interpretation of Colonial and Republican rock art, as mentioned before, studies in Bolivia, Peru, Chile, and Brazil relate rock art to ethnohistoric documents.

Recording and Analysis

Sometimes it is hard to integrate rock art into archaeological contexts, especially if no dating can be provided for a site. This is one of the reasons why rock art was not taken seriously by archaeologists of some South American countries for a long time, leaving the investigation and recording of these sites to researchers outside the archaeological mainstream. However, in the last four decades, rock art has played an ever increasing role in archaeological research, national inventories of the cultural heritage, and planning of selected sites to be protected in public facilities such as archaeological parks and whose importance is recognized or acknowledged by including them in lists of National Heritage or even World Heritage sites.

Rock art research depends on a data basis with detailed and carefully elaborated recording of sites and their paintings, engravings, or geoglyphs. Colombia, Bolivia, Brazil, Argentina, Uruguay, and Chile have improved their rock art data basis, but in some countries of South America (e.g., Paraguay), no comprehensive and professional archaeological and rock art programs have existed until very recently (Lasheras et al. 2011) (Fig. 5). Many countries have been carried out rock art sites inventories. Caribbean rock art consists of much more than 1,000 sites across the region, with the greatest concentrations in the Greater Antilles (Haviser and Strecker 2006) (Fig. 6). Over 650 sites have been reported for Venezuela (Scaramelli and Tarble 2006) (Fig. 7). In the department of Cundinamarca (Colombia) alone, some 2,000 sites have been registered, while 5,000 sites are known for the whole country (Muñoz 2006: 97, in ICOMOS 2006). Some 1,500 sites were listed for Argentina in 1988 (Renard de Coquet 1988); however, meanwhile this number might be tripled (Podestá, in ICOMOS 2006). In Ecuador, Peru, and Paraguay, some 3,000 rock art sites have been estimated (Strecker, in ICOMOS 2006), but we now believe that the number of rock art sites is in fact considerably higher. No counts of rock art sites are available at present for Chile and Uruguay (Florines *pers. comm.*).

In some South American countries, invasive recording methods (such as chalking out or making rubbings of rock engravings) were frequently used till the decades 1960–1970, and the negative effects for the conservation of rock art can still be seen in some sites. However, noninvasive recording methods (including digital photography) are

South American Rock Art, Fig. 6 Petroglyphs at Caicara, Orinoco river, Venezuela. (Photo by Franz Scaramelli)

South American Rock Art, Fig. 7 Petroglyphs in Cueva de Panchito, Dominican Republic. (Photo by Adolfo López)

being used more widely, following such models as the IFRAO and SIARB codes of ethics.

Recent analysis of South American rock art have provided insight into engraving techniques and possible lithic tools used for their production (Álvarez et al. 2001). X-Ray Diffraction (XRD), Energy-Dispersive X-Ray Spectroscopy (EDX), Total Reflection X-Ray Fluorescence (TXRF), Fourier Transform Infrared Spectroscopy (FT-IR), and Gas Chromatography/Mass Spectrometry (GC-MS) have been employed to analyze the paint on rock walls and pigments from different occupational levels of archaeological excavations in different sites in Argentina, Uruguay, Bolivia, Chile, and Brazil. For example, analysis of pigments of rock paintings at sites in Argentina has been carried out in Cueva de las Manos and Cerro de los Indios in Patagonia (Aschero 1983-1985; Wainwright et al. 2002), northern Patagonia (Wainwright et al. 2002;

Boschin et al. 2011); in Puna de Atacama region (Podestá and Aschero 2012; Yacobaccio et al. 2012) and in Quebrada de Humahuaca, both in northwestern Argentina; Brazil, in Piauí (Duarte Cavalcante 2009) Bolivia, Paja Colorada (Wainwright and Raudsepp 2008); and Chile, sites of Salado river region reveal ingredients of paint mixtures and production processes (Sepúlveda et al. 2009; Sepúlveda and Laval 2010). Few results have been reported from Uruguay.

Conservation and Management Issues

Rock art sites, which in some cases have been preserved over thousands of years, are extremely vulnerable like all open-air sites. Their conservation depends on natural deterioration factors, such as moisture, physical weathering, biological weathering, pictogram deterioration, climate, as well as destruction of rock art by human visitors which is in many cases the overall destructive factor.

For example, the Nasca geoglyphs (Peru) have been damaged by car traffic crossing the ancient lines and lack of a global management plan. Several important rock art sites in Bolivia have been destroyed by the construction of roads, and many rock art sites from Chile and Uruguay have been deteriorated by mining industry. Deforestation exposes rock art sites to the negative effects of the natural elements (Venezuela).

On the other hand, there is a recent tendency to include more and more sites in tourist routes without their previous adequate planning and administration. The tourist boom has facilitated access to sites which formerly were protected due to their isolation and inaccessibility. Some rock art sites in the Caribbean have been seriously affected by tourism developments, such as Borbón cave and Cueva de las Maravilla in the Dominican Republic, while the archaeological park at Trois-Rivières in Guadeloupe is a noteworthy exception of an area planned by archaeologists and managed for tourist visits without putting the rock art at risk. In Venezuela a few rock art sites have been implemented with visitor centers and guides available for the public (Pintado in the Amazon state; Piedra Pintado, Vigirima, Carabobo state). In Argentina, the National Institute of Anthropology (INAPL) initiated a program with the aim of preserving some rock art sites of exceptional value. The institute acts as consulting agency; the program aims at an effective collaboration with the provinces and specifically the local communities which have to play their role in managing the sites (Podestá, in ICOMOS 2006).

In theory, rock art sites are protected by state legislation as part of the nation's cultural heritage. However, reality is very different because of the lack of enforcement of existing laws. In consequence, if rock art sites are destroyed, actions are seldom taken.

An indicator of the awareness of rock art sites as cultural heritage in South America is the fact that several sites have been inscribed in the list of World Heritage by UNESCO: Cueva de las Manos (Argentina), Fuerte de Samaipata (Bolivia), geoglyphs of Nasca and Pampas de Jumana (Peru), and Serra da Capivara (Piauí, Brazil), while others have been included in the Tentative List to be considered in the future – Chamangá (Uruguay) and sites of Patagonia (Chile), geoglyph of Chirgua, petroglyphs and megaliths of Vigirima, and petroglyphs of Caicara (Venezuela), between others (Fig. 8). In these cases, rock art serves as a tourist attraction which results in the development of local communities and the economic growth of the respective region. The National Park of Serra da Capivara (Brazil), one of the densest concentrations of archaeological and rock art sites in the continent (more than 1,000 recorded sites), is considered one of the best developed archaeological parks in the Americas; it possesses 128 sites which may be visited and 400 km of pathways (Guidon 2007). At the same time, conservation measures taken may serve as a model for other rock art sites in South America. After inclusion (1999) of Cueva de las Manos (Argentina) in the World Heritage list, visitation increased four times, and today the site possesses adequate infrastructure for tourism (Onetto 2006).

Raised wooden boardwalks provide efficient measures for visitor control at the sites and, at the same time, allow visitors a convenient view of the rock art; they have been implemented at a

South American Rock Art, Fig. 8 Geoglyphs Los Pintados, Pampa del Tamarugal, Tarapacá, North Chile. (Photo by Matthias Strecker)

number of sites such as Cueva de las Manos, Cerro Pintado (Patagonia, Argentina), Calacala and Fuerte de Samaipata (Bolivia) (Strecker and Podesta 2006), and Serra da Capivara (Brazil) (Guidon 2007).

Throughout the world, local communities possess long histories of interaction with their cultural and natural environments, and their involvement is essential in the planning stage and the management of rock art sites. In many of the South American rock art sites which have been incorporated in tourist circuits – such as the abovementioned parks – local communities participated in the planning and development of tourism. Local guides may provide to visitors an authentic message concerning the importance of the site for the cultural identity of their people (e.g., Falchi and Torres 2010).

Education

Education campaigns should play an important role in the management of rock art sites, and some models exist in Venezuela (ANAR, website), Colombia (Martínez and Botiva 2002), Brazil (Fundação do Homen Americano, São Raimundo Nonato, Museu Paraense Emilio Goeldi, Belem, Fundacão Universidade Federal de Mato Grosso do Sul, Corumba), Bolivia (Strecker 2001), Peru (Strecker 2005), Chile (Museo Chileno de Arte Precolombino, website), and Argentina (Oliva and Panizza 2010; Vega and Bestard 2010).

Unfortunately, with a few exceptions, such as INAPL in Argentina, and some institutions in Chile and Uruguay, South American state institutions responsible for the protection and maintenance of archaeological sites are poorly funded and normally lack professionals in the field of administration of cultural resources. On the other hand, private organizations, such as Fundação do Homen Americano and Museu Paraense Emilio Goeldi, Belem in Brazil, SIARB in Bolivia, and Museo Chileno de Arte Precolombino, are involved in investigation, recording, and protection of sites.

While professional conservation measures at rock art sites are still rare in South America (with the exception of Serra da Capivara, Piaui, in northeastern Brazil, as mentioned), conservation and administration of rock art sites play an increasing role at rock art meetings and in academic publications (Strecker and Taboada 1995).

International Perspectives

The growing interest in South American rock art is reflected in international academic meetings held in the last decades in several countries, such as eight international rock art symposia, the 2009

and 2012 IFRAO congresses in São Raimundo Nonato, Piauí, Brazil and La Paz, Bolivia, respectively. During the last decade archaeological national congresses held in a number of countries (Colombia, Brazil, Peru, Chile, Argentina, Uruguay) included sessions dedicated to rock art studies.

On the other hand, organizations have been formed in various South American countries which promote rock art research and conservation: APAR (Peru), ABAR (Brazil), SIARB and AEARC (Bolivia), CIAR-SAA (Argentina), and CIARU (Uruguay). They all belong to the International Federation of Rock Art Organizations (IFRAO).

The inclusion of some rock art sites in the list of World Heritage (UNESCO) and others in the Tentative List, as mentioned above, places South American rock art in a worldwide perspective of sites with outstanding characteristics.

The significant advances in rock art research in this continent are also revealed in regional articles published in four volumes of the series "Rock Art Studies – News of the World" (Bahn and Fossati 1996, 2003; Bahn et al. 2008, 2012).

Future Directions

There is a great need for documentation of unrecorded rock art sites and the creation of a data basis of sites. The application of new scientific analytical methods (e.g., Reindel and Wagner 2009) and of image enhancement techniques, such as d-Stretch, will improve considerably the results of research.

Rock art studies play a major role in South American archaeological research, but in some countries have not yet been incorporated in university programs, Argentina and Chile being notable exceptions. As the awareness of the importance of rock art grows, more academic programs to record, study, and protect this cultural heritage are needed.

State and regional institutions responsible for the administration of archaeological and rock art sites have to be strengthened and must rely more on work carried out by specialists. Education campaigns should be realized in close collaboration with universities, schools, and local communities.

Considerable efforts must be made in preservation, visitor management, and interpretation of rock art sites in the future. Conservation projects are practically inexistent, with the exception of Brazil, and, to a lesser extent, Argentina, Bolivia, and Chile. There is a great need for the training of specialists in this field.

South and Southeast Asia: Historical Archaeology

Miriam T. Stark
Department of Anthropology, University of Hawai'i-Mānoa, Honolulu, HI, USA

Introduction

This essay reviews the historical archaeology of South and Southeast Asia from the inside looking out and from the outside looking in. Most historical archaeological research has conventionally taken place in the New World, where a significant divide exists between pre-Columbian and post-Columbian eras. Pan-Eurasian developments swept across South and Southeast Asia for millennia before Columbus set sail for the East Indies, so no clear break is evident between an earlier period of cultural and physical isolation and a later period of contact, disease, and colonization. To reconcile this dissonance between conventionally defined historical archaeology and the Asian sequences, this essay concentrates on two periods of intensive interregional economic interaction in South and Southeast Asia with both

archaeological and documentary records. The first period begins at the end of "prehistory" and includes the emergence of indigenous writing systems (c. 500 BCE–500 CE). The second and externally defined period is associated with the earliest European penetration in the region, starting in the late fifteenth century CE, which elsewhere is called the premodern era.

The use of both internally and externally defined time periods in this entry honors indigenous frameworks of historical archaeology, offers comparative archaeological data on European contact and colonization, and overlooks major developments in each region associated with post-Gupta and Early Medieval South Asia (Hawkes 2014a) and "Classical" Southeast Asia (e.g., Istiawan 2012: 43). By the time that European states launched their expansionist projects, many of South Asia's Medieval empires had risen and collapsed, and its northern regions were under Muslim control. By the time the first Europeans reached Southeast Asia, nearly all of its Classical agrarian kingdoms (e.g., Angkor, Pagan, Dai Viet, Majapahit, and Sukhothai) had ceded power and influence to maritime-based successor states to their south.

South Asian archaeology's first "historical" period, the "Early Historic period", lasted from the third century BCE to the fourth century CE. This period includes part of the Mauryan Empire and ends with the collapse of the Guptas; archaeologists working in southern India call it the Sangam period. Archaeologists working at large coastal cities (e.g., Sisupalgarh, Arikamedu, Pattinam, Kaundinyapura) and large Buddhist sites elsewhere (e.g., Amaravati, Sanchi, and Sarnath) from this period recover substantial evidence of interregional trade, institutionalized religion, and the region's second wave of urbanism, with localized variations (e.g., Casile 2014; Hawkes 2014b; Shaw 2013; see reviews in Fogelin 2006; Smith 2006, 2016b). Hindu and Early Buddhist texts and epics in written, oral, and material form wended their way eastward from South Asia into what is now East and Southeast Asia. Abundant interdisciplinary research has been published on the Early Historic period, by archaeologists, historians, and art historians. From this amalgam has emerged a regional understanding of the Early Historic period as an urban landscape in which the region's cities were political and economic centers and in which states, empires, and religious institutions emerged earlier in the north (see review in Morrison 1997).

The late Medieval period in South Asian archaeology is associated with the European Renaissance and period of exploration. With few exceptions like the impressive program of archaeological research at the central Indian site of Vijayanagara (work by Sinopoli, Morrison, and others), most work has been undertaken through state archaeological projects and published in the gray literature. Little synthetic or theoretical archaeological research has been published on South Asia's late Medieval period (but see Chakrabarti 2003). Until recently, historians (not archaeologists) dominated the discourse on this critical period in South Asia.

Many Southeast Asian archaeologists describe the period from the third century BCE to the fourth or fifth century CE as prehistoric ("the Iron Age") despite substantial evidence for Chinese documentary records about the region near its inception and indigenous documents by Southeast Asians by its closure. This essay employs the "Early Historic period" designation for both South and Southeast Asia for this earliest "historic" period, although Southeast Asia's archaeological record for this period was almost undocumented until the last 20 years. Like South Asia, Southeast Asia was never isolated from contact with foreigners from all directions. Yet developments from c. 1450 CE onward, which scholars call Southeast Asia's Age of Commerce or the Early Modern period, prompted social and economic transformations across the region that merit attention. This period falls within the standard time frame for historical archaeologists working in the West and yields comparative insights on processes of colonization, emergence of social stratification/class, and culture change.

Space constraints also limit the geographic coverage included in the terms "South" and "Southeast Asia." Most South Asian archaeological examples derive from either India or Bangladesh; South Asia's reach far exceeds this

area and contains myriad, complex political and economic trajectories that sources in the "Further Readings" explore in some detail. Most Southeast Asian examples come from the Indonesian archipelago or from the Mekong basin (i.e., Thailand, Laos, Cambodia), from regions where particular European nation-states engaged in commerce and, later, political control. Just as South Asia varied markedly from one region to the next, so Southeast Asia's mainland and insular regions experienced different historical trajectories based, in part, on their access to outside contacts in South or East Asia. Agrarian states emerged across most of mainland Southeast's river valleys and deltas in the early to mid-first millennium CE; the few early states that arose across insular Southeast Asia, in contrast, took several centuries longer to emerge. With few exceptions, island Southeast Asia at European contact consisted of a socially fragmented landscape of small maritime-oriented polities of variable size (Bacus 1999) that were based on a series of unstable, personalized alliances and which competed with each other for access to trade goods (e.g., Junker 2004).

Key Methodological Issues and Substantive Themes

Similar methodological and substantive issues apply to South and Southeast Asia during this Early Historic period. A burgeoning Southeast Asian archaeological literature on the period skews this essay toward Southeast Asian examples for understanding dynamics during both periods. Methodological issues affect archaeological research on both the Early Historic periods of South and Southeast Asia and the fifteenth- to nineteenth-century research and parallel those found across the broad "historical archaeology." Foremost among these is an uncritical use of documentary data to frame archaeological research in both regions. Some of South Asia's important documentary sources (e.g., the *Mahabharata*, the *Ramayana*, and the *Puranas*) were crafted during this period and influence interpretations. So do Indological studies, which emerged out of a colonial intellectual tradition that subordinated archaeological patterns to documentary accounts (Trautmann and Sinopoli 2002: 496). More archaeological challenges involve chronological sequences (e.g., Smith 2016a: 688–689), and definition (Ali 2014).

Southeast Asia's Early Historic period has also been interpreted through contemporary Chinese dynastic annals and analogies with South Asia. One reason is that most research on the Early Historic period has been undertaken by epigraphers and historians, the earliest of whom began their careers as Indologists and Sinologists. Another is that most Southeast Asian archaeologists have concentrated their efforts either on prehistoric research (particularly on the Paleolithic, Bronze, and Iron Ages) or on preservation efforts devoted to the ninth- to fourteenth-century monuments that resonate with nationalist claims and also attract cultural tourism. Recent archaeological work has produced archaeological data which challenges extant accounts on which historians have long relied.

South and Southeast Asia remained linguistically, culturally, and geographically discrete from the late first millennium BE through the mid-first millennium CE. Yet beginning in the Early Historic period, people, goods, and ideas moved across land and water in both directions. Whether inhabitants of either region immigrated to the other remains a subject of some debate; so does the precise timing of these developments. Yet several substantive themes characterize archaeological research on the Early Historic period of both South and Southeast Asia:

- Studies of urbanization (the "second wave" for South Asia after the Indus Valley Civilization and the first for Southeast Asia)
- Continuity from first-millennium A.D. cultural transformations in religion and ritual vis-à-vis emergent statecraft traditions (the study of early religious architecture and iconography and the role of trade in Buddhist propagation)
- The emergence of a pan-South/Southeast Asian interactional network that relied on maritime circulation of people and commodities through the Bay of Bengal in what is commonly described as the Maritime Silk Road

- Landscape archaeology (ritual landscapes/sacred geography and pilgrimage, agrarian landscapes and water management)

Substantive themes in the historical archaeology of the Medieval period of South Asia (ninth century A.D. to sixteenth century A.D.) and historic and classical periods of Southeast Asia include:

- The nature of imperialism (ideology, militarism, production, and distribution)
- The nature of urbanism (political economy of craft production and social organization of cities)
- The agrarian basis of states

Readers are referred to Monica Smith's (2016b) recent review, a comprehensive review of South Asian archaeology during the historical and Medieval periods.

Substantive themes in Southeast Asian archaeology of the fifteenth to eighteenth centuries, however, involve the impact of European contact on settlement, political organization, and social structure. Individual European nation-states sought control of Southeast Asia both for access to the region's own resources (particularly precious metals and spices from the Spice Islands) and for access to China through the South China Sea. The earliest contact involved the 15th/16th establishment of trade networks as Europeans competed with each other for access. During the next two to three centuries, much of Southeast Asia was taken under European control, by the Portuguese, the Spanish, and the Dutch and, in the nineteenth century, by the French, British, and Americans.

Southeast Asia's trade relationships to the East and West had begun many centuries earlier and intensified in the fourteenth to fifteenth centuries as Islamization swept through island Southeast Asia. A burst of field-based archaeological excavations on the period from c. 2500 to 1000 BP since the mid-1990s has produced more nuanced understandings of economics, settlement, and ideology during the transition to history (from c. 500 BC to AD 500) and the following period in which Southeast Asians embraced writing systems, urbanism, and statecraft (e.g., Agustijanto 2012; Bulbeck et al. 2016; Kim et al. 2010; Miksic 2000; Stark 2006). Such work yields material evidence for cultural transmission within the region, which moved along historical trade routes that have roots into the second or first millennia BC (Bellina 2014; Favereau and Bellina 2016; Hung et al. 2013).

Archaeologically recovered beads from sites throughout the maritime region have provided the most robust evidence for the timing and scale of this network (Calo et al. 2015; Carter 2015), although archaeobotanical studies are also yielding intriguing patterns (Castillo et al. 2016). Increased commerce between the region and points west accompanied this religious shift; archaeological work documents economic and settlement changes that preceded European involvement (Christie 1996; Lape 2000). Figure 1 illustrates a variety of Southeast cities that were established or expanded across the region (some in conjunction with the rise of Muslim polities), from Batavia, Manila, and Singapore to mainland capitals that functioned as inland ports like Bangkok and Phnom Penh (Miksic 2006). Only a few such centers have received archaeological attention, like Singapore and Pattani in southern Thailand.

Little archaeological research has focused on local resistance to imperialist advances, but maritime research on the Mongol invation of northern Vietnam (Kimura et al. 2014) offers an excellent case study.

Fourteenth- to fifteenth-century shifts in Ming imperial economic policy also effected changes in Southeast Asia. Archaeological research in the Philippines suggests that agricultural and political intensification occurred during this period. So did the frequency of maritime raiding and inter-valley warfare in export-oriented islands. Manufacturing industries, like stoneware production, also emerged during this time to meet regional needs (Grave et al. 2000, 2017; Gutman 2002) and rarely circulated beyond Southeast Asia's borders. Evidence of regional industrial-level production of trade goods, like high-fired ceramics, has been reported from archaeological research on myriad shipwrecks in the region (Fig. 2). Research on

South and Southeast Asia: Historical Archaeology, Fig. 1 Location of sixteenth- to seventeenth-century Southeast Asian cities involved in world commerce (drafted by Alex Morrison)

recovered materials yields insights on valuable but perishable trade goods like resin (Lambert et al. 2017), and geoarchaeological research has enabled the study of maritime sites now covered by alluvium (Guy 2017; Kimura et al. 2014).

Southeast Asian archaeologists have not only documented shifts that preceded or coincided with European contact (e.g., Kim 2013; Stark 2006). Work has now been done on the impact of European colonization: in settlement, in economic structure, and in sociopolitical organization. European colonization entailed significant settlement reorganization to meet European demands for local products and Chinese goods and changed through time in response as European colonial policies shifted. Initial resistance to European contact was intense across much of the region outside of Sinicized northern Vietnam and effected settlement changes. In eastern Indonesia's Spice Islands, the Dutch resorted to wholesale slaughter of local populations to gain control of spice-growing islands like Banda (Lape 2000). Some Filipino populations fled into the Luzon highlands to escape Spanish relocation policies of *reduccion* in the Philippines (Acabado 2016). Local identity, encoded in Philippine burials, included political and spiritual leaders (Barreto-Tesoro 2008). Work in northern Thailand illustrates migrations to upland areas in response to lowland Ayutthaya state demand for labor to support new export-oriented production systems (Grave 1995: 258).

European colonization also brought the establishment of the new Manila Galleon network that moved goods between Asia and the New World. This network linked the Spanish Philippines to Spanish Mexico through annual or biannual trips from the sixteenth to nineteenth centuries. Chinese and Southeast Asian goods sailed eastward across the Pacific to reach Acapulco, on the west coast of Mexico. These goods were exchanged for silver bullion and minted coin that returned to the

South and Southeast Asia: Historical Archaeology, Fig. 2 Location of recovered fourteenth- to sixteenth-century shipwrecks in Southeast Asia. (From Flecker 2007, with permission from John Wiley and Sons)

Philippines. More than 100 Manila Galleon expeditions set sail during this period.

European colonization in the seventeenth to nineteenth centuries not only drew Southeast Asia into the western hemisphere; it also knit Chinese commerce more closely with the west. Diasporic ethnic communities and urban ethnogenesis borne of unions between overseas Chinese and European colonials and local women were one by-product of such commerce that archaeologists have not yet studied. Melaka (Malaysia) and Dutch Batavia (Indonesia), for example, housed *Peranakan* (Chinese/Malaysian), *Mardijker* (freed slaves of Malaysian and

Indian descent), and "Topas" or "black Portuguese" (descendants of Portuguese and Flores or Solor people) communities.

Archaeological research has begun to illustrate the differential impact of European contact and colonization across the very broad and heterogeneous region of Southeast Asia. Coastal and lowland areas were most receptive to initial contact and most susceptible to subsequent colonization. That European colonization also affected sociopolitical organization in some areas seems evident from research on sixteenth-century mortuary ceramics from Calatagan, Philippines (Barretto-Tesoro 2013).

The relative paucity of archaeological work on fourteenth- to eighteenth-century Southeast Asia may explain the near-absence of key debates. Perhaps the only salient and persistent issue concerns the ethics of "historical archaeology" that retrieves shipwrecked materials through maritime commercial salvage operations. These materials provide the region's basic chronological sequence. Given the unreliability of the radiocarbon curve for this period, and the dearth of alternative dating techniques, most archaeologists date their sites through their association with locally manufactured stonewares and Chinese tradewares. Geochemical analysis of maritime trade ceramics also helps archaeologists reconstruct changing regional and international trade networks through time.

South and Southeast Asian archaeology continue to play marginal roles in studies of the fifteenth through nineteenth centuries, where additional archaeological research could contribute to the expansion and refinement of micro- and macro-histories. Ethnohistorians working through multiple European and Southeast Asian literatures have been extraordinarily interested in economic and political history, two topics on which archaeological research often yields unique insights. Scholars of the Iberian expansion currently lack archaeological knowledge of the easternmost reach of the Iberian empire: while the Spanish colonized the Philippines, the Portuguese spent time in Melaka and in East Timor.

In a global perspective, South and Southeast Asia played instrumental roles in the emergence and operation of Asia's history that coincided with the expansion of a world system that linked New with Old Worlds along both land and ocean routes. Systematic, well-designed archaeological research in South and Southeast Asia might inform on how shifts in key source zones and peripheries reflected and affected other parts of the system. These regions offer rich archaeological data for studying other topics that fall under the purview of historical archaeology, like urbanism and ethnogenesis. Almost no one has yet studied Southeast Asia's Catholic missions, which were established by the seventeenth century in the Philippines, East Timor, Vietnam, and Cambodia. Such research would provide comparative data with studies already done in the New World (and particularly in North America) on Spanish and French missions.

Future Directions

Most areas of Southeast Asia still suffer from a paucity of archaeological attention to both the earliest historic period (c. 500 BCE–500 CE) and the premodern period that began in the late fifteenth century CE. Yet archaeological scholars of European imperialism would find ample data in both South and Southeast Asia: Europeans colonized every Southeast Asian country except Thailand, and British, French, Portuguese, and Danish all established a colonial presence in South Asia. So, too, would archaeologists in the emerging study of preindustrial and early modern "capitalism." Nor has adequate archaeological attention been paid to the political economy of plantations and especially to the rise of nineteenth-century industrial plantations: rubber in Indochina, Malaysia, and Sri Lanka; sugar in the Philippines, Indonesia, and India; tea in India, Sri Lanka, and Malaysia; spices in Indonesia; indigo and cotton in India; and coffee in Indonesia, Vietnam, and Sri Lanka.

High-quality, long-term research commitment to South and Southeast Asia's fifteenth- to nineteenth-century archaeological record would help redress the current imbalance in which historians have interpreted this period. Focused local

studies on the period would complement our knowledge based on documentary data and yield insights on topics that interest historical archaeologists worldwide and that center on long-term responses of social transformation and resistance. The need is increasingly urgent, as many parts of South and Southeast Asia transition out of their status as developing countries and obliterate much of the historical archaeological record.

South Asia: Paleolithic

Parth Randhir Chauhan
Department of Humanities and Social Sciences, Indian Institute of Science Education and Research, Mohali, Punjab, India
Stone Age Institute, Gosport, IN, USA
Department of Anthropology, Indiana University, Bloomington, IN, USA

Introduction

Numerous biological and technological milestones in hominin evolution have taken place within the last 2 Ma, one of the most important being the multiple dispersals out of Africa. In that regard, South Asia can yield valuable information regarding the adaptations of various *Homo* species as it critically lies in the center of the Old World, i.e., between important paleoanthropological evidence in Africa, Europe, China, and Australasia. It also significantly straddles the eastern end of the *Movius Line* and represents the highest easternmost distribution of *rich and classic* Acheulean localities in the Old World. (The Movius Line is named after a geographic boundary first recognized and proposed by H. Movius in the 1940s. It essentially represents the easternmost boundary or dispersal extent of Acheulean technology from Africa in the west. In recent years, however, Acheulean-like tools such as hand axes and cleavers have also been found beyond the boundary, mainly in Korea and China, thus fueling debates about whether those tools are Acheulean or represent independent parallel innovations.) The region is also known for the comparative lack of early hominin fossils, a dearth of excavated sites and associated chronometric dates. Consequently, critical information such as the timing of colonization, the factors responsible for techno-cultural change, and the earliest arrival of modern humans and identifying the various hominin specie(s) that occupied the region is not known. The South Asian landmass comprises a temperate/subtropical setting, dominated by a seasonal monsoon regime prevalent since the Miocene or at least the last 18 Ma. The physiographic configuration of India induces the behavior of both the Southwest and Northeast monsoons, during the summer and winter months, respectively. South Asia or the Indian subcontinent generally encompasses the political boundaries of Pakistan, India, Nepal, Sri Lanka, Bangladesh, and Bhutan. The north is dominated by the Greater Himalaya, the Lesser Himalaya, and the Siwalik Hills, all ranges almost geographically parallel and temporally successive to each other. The Gangetic plains are followed (to the south) by the great Thar Desert (in eastern Pakistan and northwestern India) and the Vindhyan range of hills. These hills are located north of the Deccan Plateau, which is a prominent landscape of peninsular India, and include the Western and Eastern Ghats. In the past, different ecozones provided access to different types and shapes of lithic raw material. For example, for fluvial sources in the Siwalik region, rounded and subrounded quartzite and sandstone clasts dominated the Pleistocene landscape. In parts of north-central India, Acheulean assemblages were made on pink granite. In the Western and Eastern Ghats, however, the primary raw material was basalt and doleritic dikes, occurring as fragments from bedrock outcrops and waterworn clasts belonging to the Deccan volcanic Traps. Further south, in parts of Karnataka, limestone bedrock was the dominant raw material type available in the form of tabular slabs (Fig. 1). The Rohri Hills in Pakistan is a rare occurrence of more or less continuous exploitation of the same raw material source – chert outcrops – from the Lower Paleolithic to Harappan times. From the variety of raw materials exploited extensively by South Asian hominins, quartzite was one of the more dominant types used during the Lower, Middle, and Upper Paleolithic and at various types of sites contexts – quarry, factory, workshop, and occupational.

The most obvious geographic areas of entry into the subcontinent (and subsequent population movements *from* India) are Afghanistan and Pakistan to the northwest and Myanmar in the northeast. Both zones offered coastal routes, as well inland mountain passes and ecologically rich tropical evergreen and deciduous forests,

South Asia: Paleolithic, Fig. 1 Two examples of diverse rock types for stone tool manufacture: limestone blocks from Karnataka (left) and quartzite cobbles from the Siwalik Hills (inset)

without any major mountain ranges or deserts impeding potential movements. The Thar Desert may have acted as a temporary ecological barrier but also contained numerous isolated raw material sources (e.g., Jayal Gravel Ridge), and once crossed, ample outcrops of Aravalli quartzites were available on the landscape. The northeast region has a rich record of younger non-biface assemblages, most of which may be related culturally to the comparatively younger lithic industries from Southeast Asia. Similar to the Indo-Gangetic landscape in the north and northwest, however, the Bay of Bengal and the Ganges-Brahmaputra drainage system may have also acted as temporary barriers during the Late Pliocene–Early Pleistocene, due to a low occurrence of raw materials in the region and general delta environment. From the current lack of older Paleolithic evidence in NE India, the main point of entry appears to have been NW India.

Definition

Lower Paleolithic

The South Asian Lower Paleolithic evidence has been traditionally divided into two facies or types of lithic assemblages: Soanian (non- or pre-Acheulean) and Acheulean industries, both often occurring independently as well in shared geographical, geomorphological, and stratigraphical contexts. However, most of the Soanian evidence is now known to postdate the Acheulean. Stone tools across South Asia are found in stratified or surface association with fine-grained fluvial and lacustrine sediments, ferricretes, laterites, and gravel or conglomerate deposits. Most of the Indian localities have been directly dated through the uranium-thorium (^{234}Th-^{230}U) and thermoluminescence (TL) or optically stimulated luminescence (OSL) methods and include a predominance of Acheulean sites (Mishra 1995). Ages for other occurrences such as Riwat, Dina, Jalapur, Pabbi Hills, Morgaon, and Satpati Hill have been estimated using paleomagnetism and geostratigraphic correlations. With some possible exceptions in Nepal and in western India, the only unequivocal evidence of Acheulean occupation prior to the Middle Pleistocene in the subcontinent comes from Attirampakkam at between 1.07 Ma and 1.5 Ma. Other Acheulean sites have also been reported to be of comparable age but most indicate problems with the dating results, site contexts, or general interpretations. The majority of evidence in Sri Lanka belongs to the Upper Paleolithic, and some Middle Paleolithic lithic assemblages have been reported (Deraniyagala 1992), thus

signifying a relatively late colonization of that region from southernmost peninsular India, when perhaps the sea levels were significantly lower. The terminal Acheulean evidence is not well established, and the use of diminutive bifaces persisted well into the Upper Pleistocene as parts of early Middle Paleolithic assemblages (Chauhan 2009). Indeed, the Lower-to-Middle Paleolithic transition in South Asia appears to be significantly older (>300 ka) than previously thought – discussed below.

Some unique features of the South Asian Lower Paleolithic record include possible stone alignments and postholes at Paisra and stone alignments at Bhimbetka and Hunsgi. Though viewed as being controversial, a rock-shelter at Bhimbetka has yielded cupule marks thought to be contemporary with the Late Acheulean. At Singi Talav, an Early Acheulean level – layer 4 – yielded six complete and unmodified quartz crystals (though one may have some use-wear), possibly suggesting the transport of non-utilitarian objects from elsewhere. A similar example comes from the Acheulean layer at Hunsgi, which yielded almost 20 hematite pebbles, geologically exotic to the region, including one with striations interpreted as a sign of utilization. The only known premodern hominin fossils in the subcontinent may be contemporary with or younger than the Late Acheulean and come from Hathnora in the central Narmada Valley (see Patnaik et al. 2009). The Narmada fossil evidence includes a partial calvarium (possibly female) and possibly associated clavicles and a rib fragment. The calvarium was originally identified as an "advanced" *Homo erectus* and later reclassified as an archaic or early form of *H. sapiens*; most recently it has been classified as *Homo* sp. indet. Modern human fossils and subfossils are more abundant in South Asia. In India, examples are known from Baghai Khor, Bagor, Pachmarhi, Mahara-Pahar, Tilwara, Valasna, Sarai Nahar Rai, Mahadaha, Damdama, and Lekhahia. In Sri Lanka, they come from Fa Hien, Batadomba Lena, Beli Lena Kitulgala, Bellanbandi Palassa, Hambantota, Alu Galge, Ravan Alle, and Beli Lena Athula (Kennedy 2003).

The South Asian "Oldowan"

In the 1960s, A.P. Khatri was the first to argue for an indigenous origin of the Indian Acheulean from the Mahadevian industry, equated to the Oldowan, at Mahadeo Piparia in the Upper Narmada Valley. A similar claim was later made by Armand (1983) who reported a comparable assemblage at Durkadi from excavated contexts in the lower part of the valley. Subsequent research has demonstrated that the cultural sequence at Durkadi ranges only from the Middle Paleolithic to the microlithic (Chauhan et al. 2013). Numerous core-and-flake assemblages have also been reported from the Konkan coast, Karnataka, Uttar Pradesh, Bihar and West Bengal, Orissa, Andhra Pradesh, and northeastern India. Unfortunately, none of these assemblages have been dated and remain techno-chronologically undiagnostic; most appear to postdate the Acheulean (Chauhan 2009). The most systematically studied pre-Acheulean evidence in the subcontinent is also the most controversial and comes from the Siwalik deposits of northern Pakistan. The oldest archaeological evidence here is represented by the c. 2.0 Ma finds from Riwat and the 2.2–0.9 Ma old Mode 1 assemblages from the nearby Pabbi Hills. At Riwat, only 3 out of 23 specimens have been promoted as being most convincing as artifacts (Fig. 2) Rendell and Dennell (1985). The assemblages from the Pabbi Hills comprise a total of 607 lithics (Fig. 3), and the investigators chronologically divided them based on the underlying strata and associated vertebrate faunal assemblages: 102 specimens dated to 0.9–1.2 Ma, 307 specimens to between 1.2 Ma and 1.4 Ma and 198 specimens to between 2.2 Ma and 1.7 Ma. Unfortunately, the Riwat and Pabbi Hills material come from gravel and surface contexts, respectively, and comparable evidence in excavated contexts is required. The oldest paleoanthropological evidence in the subcontinent was recently reported from the Siwalik region of Masol near Chandigarh, northern India. This controversial evidence includes cut-marked fossils and "simple" choppers, both interpreted to be about 2.6 Ma (Malassé 2016). Despite using experimental cut-marks for comparisons, the cut-marks on the fossil specimens may actually

South Asia: Paleolithic, Fig. 2 The main stone tool specimens reported from Riwat, Pakistan

represent modification by the teeth of prehistoric predators or other processes such as fluvial abrasion. The contextual integrity of the artifacts also requires further substantiation as the Siwalik region is notorious for the geomorphological mixing of Siwalik-age vertebrate fossils and post-Siwalik stone tools. In short, unequivocal pre-Acheulean evidence in South Asia has yet to be excavated from primary fine-grained contexts and well-dated, such as key examples in other parts of the Old World.

The South Asian Acheulean

With the exception of northeast India and parts of Konkan Maharashtra, western Kerala, south of the Cauvery River in Tamil Nadu, and Sri Lanka, Acheulean assemblages are found throughout most of the Indian subcontinent (Pappu 2001). The South Asian Acheulean is generally divided into Early or Late developmental phases, based primarily on typo-technological features, assemblage compositions, comparative stratigraphy, and associated metrical analyses. Early Acheulean assemblages are known to comprise hand axes, choppers, polyhedrons, and spheroids, usually a lower number of cleavers (but not always) and flake tools, the predominant use of the stone-hammer technique, and a marked absence of the Levallois technique. The Early Acheulean bifaces are often asymmetrical, large with thick butts or

South Asia: Paleolithic, Fig. 3 Some representative stone tool specimens from the Pabbi Hills, Pakistan

midsections, and possess large, bold, and irregular flake scars, indicative of hard-hammer percussion. In contrast, Late Acheulean assemblages are defined by the low proportion of bifaces, the high ratio of cleavers to hand axes, the very high ratio of flake tools such as scrapers, and the extensive employment of the soft-hammer technique and the Levallois and discoid-core techniques. These bifaces are also generally smaller, thinner, and morphologically more refined, with a significant increase in the degree of retouching and controlled bifacial thinning/flaking.

The Earlier Acheulean

The Early Acheulean phase is typologically and chrono-stratigraphically represented by several occurrences, including Nepal, the Thar Desert, and parts of Maharashtra, Karnataka, and Madhya Pradesh. From the available geochronological information and comparative geology and typology, most of these assemblages appear to be older than the Brunhes-Matuyama boundary. Currently, the oldest securely dated Acheulean evidence in the Siwaliks comes from findspots at Dina and Jalalpur in northern Pakistan (700–400 ka). In the Hunsgi-Baichbal valleys (Karnataka), systematic surveys and excavations were conducted since the mid-1960s by K. Paddayya, revealing numerous occurrences belonging to all Paleolithic phases (Paddayya 2001). Probably the most important Early Acheulean site from the Hunsgi complex is Isampur, representing the first-known occurrence of in situ artifacts in a quarry context in India. Although this site was reported to be 1.2 Ma using ESR (Paddayya et al. 2002), the artifacts do not typologically match with the well-dated Attirampakkam evidence (1.5 Ma) and nor with other contemporaneous sites outside India. The region of Tamil Nadu, where stone tools were first reported in India, has been studied for over a century by various researchers (Pappu et al. 2003). The most significant site in the region is Attirampakkam, located in the Kortallayar Valley and investigated intermittently for several decades. Cultural levels at the site derive from a 7 m section and unlike the 16R dune in Rajasthan (Fig. 4) preserve only Early Acheulean and Early Middle Paleolithic levels. Preliminary lithic analyses reveal that a part of the Attirampakkam assemblage exhibits both Early and Late Acheulean characters, and the oldest evidence is between 1.07 Ma and 1.5 Ma in age from paleomagnetic and cosmogenic dating (Pappu et al. 2011). Indeed, this work signifies the first comprehensive interdisciplinary study in recent years in India. Other earlier Acheulean examples

South Asia: Paleolithic, Fig. 4 A view of the 16R dune (multicultural Paleolithic site) near Didwana and quartz crystals (inset) found in Acheulean levels at nearby Singi Talav (both in Rajasthan, NW India)

include Chirki and Morgaon in Maharashtra, Singi Talav in Rajasthan, and Pilikarar in Madhya Pradesh.

The Later Acheulean

The South Asian Late Acheulean sites occur in greater numbers, possibly reflecting population dynamics and associated land-use intensity during the later Middle Pleistocene. This evidence marks the earliest, but undated, employment of the prepared-core and Levallois technology in the region, which are in the form of discoidal cores and the Victoria West technique, as well as the initial production of large blades at sites such as Bhimbetka. The Rohri Hills in southern Pakistan are one of the few South Asian Lower Paleolithic occurrences produced on chert (Fig. 5), and the assemblages come from numerous localities comprised of hundreds of artifacts. In Nepal, the site of Gadari indicates occupation along the banks of the Babai River, as the hand axes were recovered from the basal gravels of the alluvium, the oldest period of the Dang dun, a shallow intermontane post-Siwalik Valley (Corvinus 2006). Most of the South Asian Late Acheulean evidence, however, is located in central and peninsular India, including parts of Rajasthan, Gujarat, Maharashtra, Madhya Pradesh, Bihar, Karnataka, Andhra Pradesh, and Tamil Nadu (Pappu 2001). Some of the best-known Late Acheulean assemblages in north-central India come from Bhimbetka, where hundreds of rock-shelters (many with rock paintings) are situated in a hilly and forested area in Madhya Pradesh (Misra 2001). Trenches in a cave (III-F-24) yielded a 3.8 m Lower and Middle Paleolithic sequence as well as Mesolithic material at the top (Fig. 6). It is unclear exactly when hand axes and cleavers disappeared from the South Asian archaeological record but occur as late as 110 ka and 60 ka in central and western India, respectively.

The Middle Paleolithic

The South Asian Middle Paleolithic has been clearly defined from a large number of occurrences found throughout the entire region, and H.D. Sankalia was the first to formally recognize and define the South Asian Middle Paleolithic at Nevasa (Pal 2002). However, separating the Middle Paleolithic horizons from the terminal Acheulean ones has proved to be challenging because the Levallois technique (Fig. 7) and other forms of prepared-core technology originate in the Late Acheulean phase of the subcontinent. Additionally, the South Asian Middle Paleolithic sites often overlap geographically with the Late Acheulean occurrences and indicate successful adaptations and exploitation of a range of ecological and topographic settings. Older assemblages often appear to contain diminutive hand axes, and

South Asia: Paleolithic, Fig. 5 Example of an Acheulean biface on chert in the Rohri Hills, Pakistan

South Asia: Paleolithic, Fig. 6 One of the excavated rockshelters at Bhimbetka in central India

South Asia: Paleolithic, Fig. 7 A Levallois flake from the Narmada Basin, central India

younger assemblages may have an increasing blade component. These observations, however, need to be verified through a more robust chronological framework. The features that distinguish Middle Paleolithic assemblages are the following: (a) a decrease in size of the artifacts; (b) a noticeable shift from large Acheulean bifaces to more smaller, specialized tools; (c) an increase in the prepared-core technique; and (d) a preference for fine-grained raw material (such as quartz, fine-grained quartzite, chert, jasper, chalcedony, flint, agate, cryptocrystalline silica, lydianite, and bloodstone). The South Asian Middle Paleolithic sites vary in their assemblage compositions, which generally include cores, choppers, discoids, scrapers, flakes, points, debitage, and so forth. Some well-studied stratified examples are Nevasa in Maharashtra and Samnapur in Madhya Pradesh, evidence from the Kortallayar Basin in Tamil Nadu, and the Jwalapuram lithic assemblages associated with Younger Toba Tephra in Andhra Pradesh (Petraglia et al. 2007). In Rajasthan, they have been found to be stratified in stabilized paleo-sand dunes and fluvial contexts (e.g., Luni and Berach Basins; 16R dune at Didwana). Absolute dating methods on different materials from different sites suggest that the Indian Middle Paleolithic is provisionally bracketed between 385 ka and 38 ka, although assemblage compositions vary in frequency over time including bifaces of different sizes, Levallois elements, points, and blades.

The latest research on the South Asian Middle Paleolithic demonstrates that the technological transition following the terminal Acheulean is much more complex and older than previously thought for this region. Akilesh et al. (2018) report new data on the Early Middle Paleolithic from Attirampakkam dated to between 385 and 74 ka using infrared-stimulated luminescence. These

assemblages include predominantly diminutive bifaces, Levallois and tanged points, Levallois cores, and a few blades, all of which are distributed throughout the stratigraphy in varying frequencies. The bottom-most assemblage is currently the oldest Middle Paleolithic evidence outside of Africa and may suggest multiregional evolution of this technology across the Old World (e.g., the Mousterian by the Neanderthals). Earlier, some younger Indian Middle Paleolithic sites (e.g., Jwalapuram, Kataoti) were interpreted to have been a result of modern human dispersals. While this new study does not reveal which hominin species was responsible for the Indian Early Middle Paleolithic, it clearly challenges previous hypotheses that (i) the Indian Middle Paleolithic is younger than 120 ka and (ii) that it was brought in exclusively by *Homo sapiens*. The most likely possibility is that the oldest South Asian Middle Paleolithic assemblages were produced by archaic hominins who survived late in India before being replaced by modern humans with younger and more advanced technologies soon after 60 ka. However, one additional possibility should not be ruled out: that there were multiple waves of Middle Paleolithic technological dispersals across the Old World by different species over time – at first by archaics and later by moderns. A major challenge in Paleolithic archaeology has been, and still is, to reliably differentiate between these mixed Middle Paleolithic technologies (indigenous vs. dispersed).

Though difficult to classify exclusively as Middle or Upper Paleolithic, archaeological evidence at about 45 ka is represented by Kalpi in the Ganga Plains which yielded vertebrate fossil remains as well as core tools and by Site 55 in Pakistan in loess context. Also in Pakistan, Sanghao Cave of Mousterian and Upper Paleolithic cultural affinities also shows broadly comparable ages ranging from 42 ka to 22 ka.

The Upper Paleolithic

The South Asian Upper Paleolithic is also not clearly defined, due to lack of absolute dates and detailed technological analyses/classification. This entity was first recognized based on specific tool types already known from Africa and Europe. Its dominating and defining features include a notable increase in the production of more specialized tools such as blades, burins, borers, and, at some sites, an early occurrence of microliths. Additional tool types of this period include flakes, knives, awls, scrapers, and cores including cylindrical types, choppers, and bone tools. At Bhimbetka, for example, end scrapers dominate the Upper Paleolithic assemblages and are often made from the bases of blades and burins. The use of pressure flaking and the soft-hammer technique for flake detachment appears to increase significantly as compared with the older lithic traditions. The degree or intensity of retouch also appears to increase in general. The South Asian Upper Paleolithic shows a greater degree of regional typo-technological variation as well as an increase in different types of scrapers (e.g., steep, convex, convergent) and backed blades. Additional unique features include (a) the exploitation of ostrich eggshell fragments for making beads at Patne, Mehtakheri, Bhimbetka, Batadomba Lena, and Jwalapuram rock-shelter and non-utilitarian artifacts such as engraved geometric or crosshatched patterns; (b) possibly the oldest prehistoric shrine in the region at Baghor II; and (c) stone platforms at Bhimbetka and Site 55, and bone harpoons from the Belan Valley and Jwalapuram rock-shelter. Some of the later Paleolithic assemblages, such as Badatomba-lena and Sites 49 and 50 (Sri Lanka) and Jwalapuram rock-shelter (India), comprise the earliest geometric microlithic evidence in South Asia (see Clarkson et al. 2009). A sound chronological framework for the South Asian Upper Paleolithic is lacking, but a broad estimate can be provisionally assigned as 50 ka to 15 ka before the Mesolithic proper starts. The best-known sites (or stratigraphic sequences reported with Upper Paleolithic assemblages) include the Son Valley sites and the Bhimbetka rock-shelters (shelters III-F-23 and III-A-28) in Madhya Pradesh, the Kurnool caves and several river basins in Andhra Pradesh, the Belan Valley sites in Uttar Pradesh, the Singhbhum region of Bihar, Patne in Maharashtra, Mehtakheri in the Narmada Valley, the Budha Pushkar region in Rajasthan, the Rohri Hills in Pakistan, the Chota Nagpur region in

Bihar, the Sanghao rock-shelter and Site 55 in Pakistan, and Batadomba Lena and Fa Hien Cave in Sri Lanka. Rock art and other forms of symbolic behavior appear to have started during this time before becoming prolific during the subsequent Mesolithic phase (Table 1). It is important to note that some Upper Paleolithic evidence and the earliest microlithic assemblages appear to mix and chronologically overlap across South Asia; this evidence has been labeled as Late Paleolithic (James and Petraglia 2005). In some regions, a classic or exclusive Upper Paleolithic record is completely missing, and the Middle Paleolithic evidence is followed directly by microlithic assemblages.

The Siwalik Hills and the Soanian Industry

The most enigmatic and prominent non-bifacial techno-complex is represented by the Soanian industry, found throughout the Siwalik Hills region in Pakistan, India, and Nepal. As first defined by de Terra and Paterson (1939) from the Soan terrace sequence in northern Pakistan, Soanian artifacts were manufactured on quartzite pebbles, cobbles, and occasionally on boulders, all derived from various fluvial sources on the surrounding landscape. These assemblages generally comprise varieties of choppers, discoids, scrapers, cores, and numerous flake types (Fig. 8), all occurring in varying typo-technological frequencies at individual sites. Such attributes as bifacial reduction, acortical finished tools, extensive platform preparation (i.e., facetted platforms), and plan form and lateral symmetry are absent within the Soanian. The primary issues in accurately characterizing Soanian assemblages include lack of primary contexts and absolute dates and low numbers of diagnostic assemblages. The dynamic sedimentary and tectonic history of the Siwalik region has prevented preservation of Paleolithic sites. Most occur in non-dateable surface contexts with stray artifacts strewn randomly across Siwalik landscapes. Excluding some localities in the Soan Valley of Pakistan, the site complexes of Guler (Beas Valley) and Toka (Kala Amb area) in India, and the Arjun-3 site in Nepal, Soanian assemblages rarely comprise more than a few dozen artifacts. Rendell and colleagues (1989) have shown the Soanian "terraces" observed by de Terra and Paterson to be erosional features in the Soan Valley, rather than true river terraces. Although this challenges the validity of Soanian technological progression based on terrace sequences, current geological evidence suggests a post-Acheulean age for the earliest Soanian assemblages, also supported by preliminary dates from Arjun-3 in Nepal (e.g., Zöller 2000). Although the techno-cultural origins of the Soanian and associated chronologies are obscure, it is clear that the regionally dominant raw material (fluvially rounded quartzite clasts) and associated technology continued to be manifested into the Holocene.

Historical Background

The development of Quaternary and Paleolithic research in India can be divided into three phases: (1) from 1863 to 1964, (2) from 1964 to the early 1980s (see Korisettar and Rajaguru 1998), and (3) from the 1980s to the present day. During the first phase, inferences relating to paleoclimates and paleoenvironments depended on the characteristics of lithological units (such as coarse-grained and fine-grained clastic sediments) and the associated faunal material. Methodology and interpretative frameworks that were prominent in Europe were applied to the Indian context (most especially the glacial climatic sequence). Due to this massive influx of European influence between 1940 and 1960, many regional surveys were conducted to eradicate theoretical gaps, which included Pleistocene chronology and cultural successions. The 1960s formed a decade of important methodological and theoretical applications in the earth sciences and archaeology, all over the world. Numerous geographic zones of study were introduced, and they included littoral, aeoline, lacustrine, and offshore environments. The first discovery (in 1863) of Lower Paleolithic artifacts was made at Pallavaram near Madras (now Chennai) by Robert Bruce Foote (Kennedy 2003). He was probably the first investigator to attempt establishing their ages as well as reconstructing contemporary climatic conditions and also the

first to apply a geoarchaeological perspective with an emphasis on site formation. A few decades later, the Yale-Cambridge expedition was launched by de Terra and Paterson (1939) to seek evidence of Pleistocene glaciation phases in the sub-Himalayan region and to highlight its impact on early human cultures, both in concordance with the European model. Following their fieldwork in the Kashmir Valley (Jhelum), on the Potwar plateau (Soan Valley in modern-day Pakistan, discussed below in greater detail), in the central Narmada Valley (between the towns of Hoshangabad and Narsinghpur), and around Chennai, they arrived at a fourfold glacial-interglacial model first established in Europe in 1909. This glacial-interglacial model became a standard for subsequent Pleistocene research in India and prevailed for several decades, until revised by other researchers in the 1980s. In the greater part of the twentieth century, H. D. Sankalia and his colleagues and students placed great emphasis on correlating paleoenvironmental parameters and corresponding technological and behavioral adaptations of early hominids in the subcontinent. An interesting point to be noted is the emphasis placed (at that time) on river valleys and basins for the investigation of Paleolithic sites. Later efforts were directed at sites between

South Asia: Paleolithic, Fig. 8 Representative stone tool specimen from a Soanian site in the Siwalik Hills of northern India

river valleys or away from river valleys and expanded the potential of these sites in peninsular India (Fig. 9 and Table 2). Comprehensive multidisciplinary approaches have been applied only in the last two decades and at very few Paleolithic sites in South Asia. As a result, it is unknown whether various transitions represent technological influences of incoming populations (dispersal of *Homo sapiens* from Africa) or represent indigenous biocultural continuities (independent of external influence). These dynamic transitions probably reflect the collective impact of a suite of factors: demography, raw material type, topographical prominence, water resources, cognitive capabilities, mobility and settlement patterns, and subsequent hominin dispersals from peripheral regions. Research efforts in the last few years have centered on identifying technological dispersals from Africa, pinpointing Early Pleistocene occupations, pinpointing the initial arrival of modern humans, understanding the regional ecological impact of the Toba super-eruption at 74 ka on hominin populations, and establishing the earliest occurrence of microlithic technology.

Key Issues/Current Debates

Most regions of the subcontinent contain assemblages belonging to almost all three Paleolithic phases of techno-chronology, reflecting continuous occupation in various regions but at different levels (e.g., Rohri Hills in southern Pakistan, Hunsgi-Baichbal basins in southern India, the Son Valley in Madhya Pradesh). However, continuous stratigraphic and archaeological sequences from the Lower Paleolithic to the Upper Paleolithic and Mesolithic phases at single

South Asia: Paleolithic, Fig. 9 Map of key paleoanthropological localities in South Asia

locations are rare in South Asia. Exceptional occurrences have been reported from the 16R dune (Rajasthan) and the Bhimbetka and Adamgarh rock-shelter complexes (Madhya Pradesh), all of which preserve continuous archaeological sequences. Some sites have shorter behavioral sequences, such as Patne (Maharashtra), which has Middle and Upper Paleolithic and Mesolithic assemblages but no evidence of Lower Paleolithic occupation. Though these sites have variably preserved multiple techno-chronological horizons ranging from the Lower Paleolithic to the Mesolithic, the sequences are not stratigraphically (i.e., chronologically) continuous. Some of these occurrences represent no visible hiatus during the Late Acheulean to Middle Paleolithic transition, while other sites have yielded sterile layers between cultural horizons. The South Asian Middle Paleolithic and South Asian Upper Paleolithic may represent a combination of indigenous development as well as technological and behavioral influences from incoming populations. The Lower-to-Middle Paleolithic transition is often defined by some by the presence/absence of bifaces. Likewise, the regional Upper Paleolithic-to-Mesolithic

South Asia: Paleolithic, Table 2 Key South Asian paleoanthropological sites and their significances. For further details and relevant reference sources, see Chauhan (2009) and other citations in text

Site name	Age	Significance
Riwat	– c. 2.0 Ma	Possibly the oldest Oldowan evidence in South Asia
Pabbi Hills	– 2.2–1.0 Ma	Oldest Mode 1 evidence in contextual association with vertebrate fossils
Attirampakkam	1.07–1.5 Ma	Oldest Acheulean occurrence in South Asia; possible bovid and elephant footprints and shell impressions preserved
Isampur	– 1.27–0.73 Ma	First-known Acheulean quarry
Bhimbetka	– Late Middle Pleistocene to Holocene	Largest, lengthiest, earliest, and stratified rockshelter complex with rock art
Hathnora	– Late Middle Pleistocene or Late Quaternary	Oldest premodern fossil hominin; attributed to various species of *Homo*
Adi Chadi Wao	69 ka	Youngest dated handaxes
Jwalapuram	c. 74 ka	Oldest well-dated Middle Paleolithic assemblages and in association with Younger Toba tephra (note: below YTT only; the assemblages above YTT are in secondary context)
Kurnool Caves	– Late Quaternary	Earliest known use of controlled fire, bone tools, cutmarked bones
Patne	25 ka	Incised ostrich eggshell fragment

transition is becoming difficult to characterize because the antiquity of microlithic technology is being pushed back. In fact, there is high typo-technological variation across the subcontinent after 400 ka with respective sites having variable numbers (including complete absence at times) of Large Flake Acheulean bifaces, diminutive bifaces as well as flake-dominated, blade-dominated, and microlithic-dominated assemblages (Fig. 10). This technological diversity appears to increase after about 120 ka and reaches its peak with contemporaneous Middle Paleolithic, Upper Paleolithic, and microlithic typo-technologies at about 45 ka, at Kalpi (northern India), Site 55 (Pakistan), and Mehtakheri (central India), respectively. The absence of Paleolithic evidence in some parts of the Indian subcontinent may be related to unique climatic and topographic features. For example, parts of northeastern India are known to receive the highest amount of rainfall in the world, a climatic feature that may have affected regional environmental conditions during the Pleistocene, including sedimentation rates, seasonal raw material availability, and access to required resources for subsistence (as compared to other regions of the subcontinent). One reason for the dearth of Paleolithic archaeological evidence in such regions may be poor visibility for survey purposes or a limited occurrence of time-specific deposits in this thickly vegetated zone.

Many tool types within the South Asian Paleolithic are also known from other regions of the Old World, thus suggesting broad similarities in their overall functional and behavioral aspects, as well as shared subsistence strategies. At the same time, the comparatively low profile of specific tool types, such as classic tanged bifacial (projectile) points (Costa 2012) and preferential Levallois elements, may reflect the absence of associated behaviors (e.g., hunting of large mammals with hafted points on short thrusting spears) in the subcontinent. No convincing evidence of butchery has been clearly demonstrated in South Asia earlier than the evidence from the Kurnool Caves and possibly Kalpi at about 45 ka. Though rare, there appear to be some regional typo-technological variants within the South Asian Paleolithic. For example, the cleaver manufacturing technique from Chiri-on-Pravara is not found anywhere else in the subcontinent. Likewise, the Middle Paleolithic Jamalpur industry from Bihar shows higher than "normal" frequencies of end scrapers, notched tools, and denticulates, as well as typo-morphologically unique knife and scraper types. The paleoanthropological record of the island country of Sri Lanka is comparatively less well known but has a significant bearing on the

South Asia: Paleolithic, Fig. 10 Key Middle/Upper Paleolithic and early microlithic assemblages across South Asia (385–35 ka). Available dates are indicated next to site locations, and the undated assemblages are presumed to be younger than 100 ka. Site numbers: 1 = Sanghao Cave; 2 = Site 55; 3 = Toka; 4 = Arjun-3; 5 = Chancha Baluch; 6 = Ongar; 7 = Luni; 8 = 16R; 9 = Katoati-a; 10; Katoati-b; 11 = Budha Pushkar; 12 = Berach; 13 = Kalpi; 14 = Son and Belan valleys (including Dhaba); 15 = Samnapur; 16 = Adamgarh; 17 = Bhimbetka; 18 = Mehtakheri; 19 = Orsang Valley; 20 = Adi Chadi Wao; 21 = Hiran Valley including Adi Chadi Wao; 22 = Patne; 23 = Singhbhum; 24 = Ramayogi Agraharam; 25 = Hunsgi-Baichbal; 26 = Kaladgi Basin (including Lakhmapur); 27 = Konkan; 28 = Jwalapuram Toba localities; 29 = Jwalapuram 9 rock-shelter; 30 = Kurnool Caves; 31 = Gunjana Valley; 32 = Attirmpakkam; 33 = Batadomba-lena; 34 = Ratnapura industry; 35 = Kana and Mahadebbera. (Modified after Chauhan et al. 2017)

evolution of modern humans in the subcontinent. Some of the most well-preserved South Asian fossils of modern *Homo sapiens* come from various cave deposits in Sri Lanka such as Fa Hien Cave. Renewed paleoanthropological research is critically required, however, to identify and date the earliest occupation in this region, which currently appears to be no older than 30 ka. The Ratnapura region in the southwestern wet lowlands (Deraniyagala 1992) has yielded quartz and quartzite lithic artifacts, but these remain undated and ambiguous.

Future Directions

Despite over a century of Paleolithic research in South Asia or the Indian subcontinent, a large number of important issues require to be addressed and explained. Some examples include (a) the lack of premodern hominin fossils as compared with other Old World regions, (b) the lack of unambiguous Oldowan evidence (especially if South Asia was a route during Out of Africa I migration from eastern Africa to SE Asia during the early Pleistocene), (c) the potential impact of the Toba super-eruption at 74 ka on regional (and global) climate and hominin adaptations/survival, (d) the number of dispersals and hominin species in the region during the last 2 Ma, and (e) specific subsistence strategies and land-use patterns in relation to the differing ecologies across the entire region. More systematic surveys, multidisciplinary investigations, and rigorous absolute dating projects are crucially required to address all of these problems and related questions (see Dennell 2000–2001). A more increased focus on paleoanthropology in South Asia is all the more important as numerous areas with Paleolithic evidence are under constant threat from population increase, growing infrastructure, widespread agriculture, and other destructive agents.

On the lack of hominin fossils: One of the most significant deficiencies in South Asian paleoanthropology is the virtual lack of hominin fossils older than the Upper Pleistocene. This insufficiency appears to be related to a number of possible factors: (1) geological factors such as low rates of preservation and high rates of erosion, (2) the fossils are exposed or preserved in very rare contexts and have not been recovered as of yet, (3) the fossils, especially fragmentary or weathered specimens, have not been recognized as being hominin by nonspecialists, since most investigators in the field are archaeologists, prehistorians, and geologists. Qualified physical anthropologists have rarely carried out long-term and systematic surveys for hominin fossils in South Asia.

On lack of unequivocal Oldowan evidence: Though numerous "Oldowan" assemblages have been reported throughout the subcontinent, unequivocal evidence (if any) continues to remain elusive. Because there is a considerable faunal overlap between the Siwalik Hills region and various early Homo sites, it appears that the Pliocene conditions in India during the Pinjore Fm. times were conducive to possibly allow dispersion of early hominin through the region. Moreover, sediments older than the Middle Pleistocene occur only in pockets south of the Siwalik Hills, suggesting that associated Oldowan evidence has not been preserved in primary context or is deeply buried at places. If early hominins with Oldowan technology passed through this region on the way to SE Asia, associated evidence should be (theoretically) preserved in South Asia, even if marginally.

On the possible impacts of the Toba super-eruption: The Toba volcano, located in Indonesia, erupted at least three times in the last 1 Ma. The largest eruption, or super-eruption, is known to have occurred at ~74 ka, and resulting ash was widely deposited in India due to the wind direction following the eruption. Primary deposits of this ash or tephra can be used as chrono- stratigraphic marker in the field. Current debates are centered on the potential ecological impact(s) of the eruption on Indian Pleistocene flora, fauna, and hominin populations (Williams 2012). A key hindrance has been the challenge in finding undisturbed Paleolithic assemblages in

stratigraphic association above, below, and within primary context Younger Toba Tephra deposits.

South, Stanley A.

Russell K. Skowronek
University of Texas-Pan American, Edinburg, TX, USA

Basic Biographical Information

Stanley A. South is one of the most complex and fascinating archaeologists of the past 60 years. Born on February 2, 1928, Stanley was the only son among the four children of Austin E. South and Mae Belle Casey South of Boone, North Carolina. A child of the Great Depression, South grew up in a loving multigenerational family filled with music, singing, poetry, art, and a profound respect for the people and culture of the Appalachian Mountains. In 1934 when others were migrating westward, the South family traveled across the United States to Carlsbad Caverns, the Grand Canyon, Yosemite, and the Chicago World's fair. His formative years ended with service in the US Navy during the final months of WWII followed by photography school and a brief stint as a professional photographer before matriculating at Appalachian State Teachers College (now Appalachian State University) in Boone, NC (1946–1949). After graduation South did some acting and was a public school teacher in a junior high school in Greensboro, NC. There he taught a class on the American Indian, and he began recording archaeological sites in the region.

It was as a student at Appalachian State that South was first exposed to Darwinian evolutionary theory and the then cutting-edge cultural evolutionary theorists Julian Steward and Leslie White. South found his muse in the evolutionary approach and its application to anthropology. He left teaching and entered the graduate program in anthropology at the University of North Carolina. There, under the tutelage of Joffre Coe, he fully embraced the application of evolutionary theory in archaeology (South 1955). Fifty years later he is still an outspoken proponent (South 2005; South and Green 2005).

Major Accomplishments

Over the past five decades, South has made significant contributions in prehistoric and historical archaeology of the Carolinas and the interpretation of same to the general public. This included work at such prehistoric sites as Town Creek Indian Mound in North Carolina and at Charles Towne Landing in South Carolina. He has worked on English (e.g., Brunswick Town [South 2008]; Bethabara [South 1999]; Charles Towne Landing [South 2005]; Ninety-Six), French (Port Royal), Spanish (Santa Elena), and American (Edgefield, Columbia [South 2010]) sites in the Carolinas dating from the sixteenth to twentieth centuries. Known for his exacting field techniques, South drew on his background in photography and drawing and admonished his colleagues to do likewise. This would include the quantifying of findings and their interpretation to the public through reconstruction (South 2002). Significantly South was an early proponent for the timely analysis and reporting of fieldwork. Over the course of his career, he has completed more than 200 reports, articles, monographs, and books detailing his findings. He was the founder of the Conference on Historic Sites Archaeology in 1959 and a cofounder of the Society for Historical Archaeology in 1967. Through his efforts and the support of the Conference on Historic Sites Archaeology, South compiled and published 15 volumes of papers delivered at the annual meetings and later created two other publication series, *Volumes in Historical Archaeology* and *Historical Archaeology in Latin America*. These number 51 and 16 volumes, respectively.

Just before his fiftieth birthday in 1977, South crossed a watershed in his career with the publication of *Method and Theory in Historical Archaeology*. In it South the anthropologist said that to go beyond simple antiquarianism, we must explicitly engage in scientific archaeology. That is, its foundation must rest on evolutionary theory, using the hypothetico-deductive-inductive paradigm (South 1977: 6). Simply put, the humanistic and particularistic paradigms did not meet the criteria necessary for scientific research.

By using the scientific paradigm, South believed that the historic archaeological record would reveal valuable patterning linked to behavior. Thus began his search for patterning to demonstrate that. Built on two decades of research on English-colonial era sites in the Carolinas, its quantitative approach led to the definition of a variety of material patterns reflecting the behaviors associated with the resident cultures of the past. Embraced by the field for making explicit what was implicit, it would be required reading for a generation of students and would transform the field (South 1978). Today pattern recognition is a de rigueur aspect of the methods associated with historical archaeology. While many have turned to humanistic post-processual "storytelling" or other impressionistic approaches, South and many others continue to recognize that pattern delineation holds great promise for comparing differing cultural adaptations in similar natural and social environments. South sums up his basic philosophical belief as "Science: Seek life's truths to set you free" (Joseph 2010: 135, 141).

Beginning in 1978 and continuing for the next quarter of a century, South worked at the sixteenth-century capital of Spanish La Florida Santa Elena. Now a National Historic Landmark, the site, located on the US Marine Corps Recruit Depot, Parris Island, South Carolina, is one of the most completely investigated and best preserved sixteenth-century town sites in the Americas. A detailed publication on the European material culture from the site is widely cited throughout the hemisphere (South et al. 1988). Information from this site will continue to influence our knowledge of sixteenth-century adaptations for decades to come.

Stanley South has been repeatedly honored for his many contributions to the field of historical archaeology, regional history, and scholarship. In 1987 South was awarded the J. C. Harrington medal in Historical Archaeology, the most prestigious award the profession has to offer by the Society for Historical Archaeology (Ferguson 1987). This was followed with the "Order of the Palmettos" and "The Old North State Award" by the states of South and North Carolina. In 1997 he was awarded an Honorary Doctor of Humanities

from the University of South Carolina Trustees for his then four decades of research.

In 2012, at the age of 84, Stanley South retired after 43 years at the South Carolina Institute of Archaeology and Anthropology in Columbia, South Carolina.

Southeast Asian Ceramics

Tse Siang Lim
Spring Hill, QLD, Australia
School of Archaeology and Anthropology, Research School of Humanities and the Arts, College of Arts and Social Sciences, Australian National University, Canberra, ACT, Australia

Introduction

The origin of ceramics and their associated technologies – that of the manipulation of clay and pyrotechnology – in Southeast Asia is an important archaeological question that has yet to be researched in detail. Recent fossil and archaeological evidence suggest that the initial colonization of Southeast Asia by *H. sapiens* must have occurred sometime between the *terminus ante quem* of their arrival on Sundaland around 73 ka BP and that of their eventual migration to Sahul at 65 ka (Bellwood 2013: 67, 72, 2017: 89–92; Clarkson et al. 2017; Westaway et al. 2017), with a more conservative estimate placing this migration between 45–50 ka BP (O'Connell et al. 2018). It was to take, however, at least another 65,000–60,000 years before the emergence of the first ceramic artifacts within the bands of hunter-gatherer societies populating the region at that time. This perceptibly long delay in the development of ceramic technology in Southeast Asia is even more perplexing, given that the earliest ceramic artifacts in southern China at the cave sites of Xianrendong (仙人洞 Xiān Rén Dòng) in Jiangxi (江西 Jiāng Xī) province and Yuchanyan (玉蟾岩 Yù Chán Yán) in Hunan (湖南 Hú Nán) province date to c. 20 ka BP and

c. 18 ka BP, respectively (Boaretto et al. 2009; Cohen et al. 2017; Kuzmin 2017; Wu et al. 2012).

To date, the earliest evidence for ceramic technology is found at the Spirit Cave in Northwest Thailand which has been dated to around 7500 BP (7622 ± 300 BP, cal. BP 7193-5900), but this early Holocene date has been disputed in recent years (Gorman 1970: 96, 98; Lampert et al. 2003; Solheim II 1972; White 2004). Outside the Spirit Cave, ceramic artifacts recovered from isolated hunter-gatherer Hoabinhian contexts at Banyan Valley Cave (5360 ± 120 BP, cal. BP 4406-3960) in Thailand, Laang Spean (c. 4290 BC or 6240 ± 70 BP, cal. BP 5616-5461) in Cambodia, Da But in Vietnam (6540 ± 60 BP, cal. BP 5616-5461), and the Pada-Lin Caves in Myanmar (7740 ± 125 BP, cal. BP 6864-6393) collectively document the mid-Holocene appearance of ceramic technology in Mainland Southeast Asia (Bronson and White 1992a: 495–496, b: 478; Bui 1991: 128; Ha 1984–1985: 135; Mourer and Mourer 1971: 36; Nguyen 2005: 91; Reynolds 1992: 84; Zeitoun et al. 2012: 530). In comparison, the earliest known earthenware ceramics found in Island Southeast Asia to date are located at the sites of Sanga Sanga in southern Philippines (6650 ± 180 BP, cal. BP 5912-5291), the Niah Caves in west Malaysia (6850 ± 600 BP, cal. BP 7056-4460), as well as an assortment of plain and burnished pottery recovered in East Timor has been estimated to date to a much later horizon of 4500-3700 BP (Bronson and White 1992a, b; Glover 1986: 204; Solheim II 2003: 3). (Recalibrated by present author with Calib7.10 using IntCal13 curve at 2 Sigma, with the range covering largest relative area under probability distribution cited; see Stuiver and Reimer 1993.)

Definition

For heuristic purposes, "Southeast Asian ceramics" refer to any form of ceramic artifacts – typically, but not limited to, vessels – produced by potters and artisans within the geographical boundaries of the region presently occupied by the 10 member states of the Association of Southeast Asian Nations (ASEAN). In this article, earthenware ceramics refer to any clay artifact fired between 800–1000 °C, whereas stoneware ceramics are usually produced around 1200–1300 °C whereupon clay minerals melt and fuse into a glass-like matrix in a process known as vitrification (Rice 2015: 3–6). As with the rest of the world outside of China during the premodern period, Southeast Asian potters did not produce true porcelain but nonetheless, developed the technology and respective *chaînes opératoires* for the production of a wide variety of "porcelaneous" glazed stoneware ceramics that resemble the significant quantities of Chinese porcelain imported into the region during the historical period.

Historical Background

Prehistoric Ceramics in Southeast Asia

The earliest pottery decorative technique applied on "Hoabinhian" ceramics appears to be paddle-impressions of either "vine or bark" (Ha 1991: 135), followed shortly after by a variety of other techniques including paddle-impressions with basket- or cord-marked patterns, carved-paddle impressions, cord or net-marking, incising, burnishing, slipping, and appliqué (Solheim II 2003: 1–3). These early decorative techniques are hypothesized to be subsequently integrated and distributed across Southeast Asia by the "Neolithic Nusantao Maritime Trading Network" (Solheim II 2006). Both the "Sa-Huynh-Kalanay" and"'Bau-Malay" pottery traditions as well as that of the "Lapita" in the Pacific region have been hypothesized to have developed out of this common "Neolithic" ancestry which, in turn, is thought to have originated in Southern China (Solheim II 1990, 2003: 14–21). Named by Solheim after two prehistoric sites in Vietnam and the Philippines, respectively, he defined the "Sa Huynh-Kalanay" tradition primarily by its decorative motif that typically includes "scallop designs on carinations and rims, friezes of paired diagonals, sequences of alternating triangles and horizontal 'S' interlocking triangles and rectangles, and repeated scrolls or waves" (Favereau and Bellina 2016: 220).

Thereafter, the "Bau-Malay" tradition – characterized specifically by a range of decorative motifs applied using the carved-paddle impressed technique – is observed to gradually replace the "Sa-Huynh-Kalanay" tradition during the first millennium AD in Island Southeast Asia and established itself firmly in the southern Philippines, west Borneo, western Indonesian islands, and the Malay Peninsula from AD 700 onwards (Solheim II 1990: 28–29). Aside from the "Bau-Malay" tradition, "Tanjong Kubor" earthenware – named after the area in Sarawak where many sites with this pottery were found – is the only other major pottery typology in Island Southeast Asia which affiliates earthenware ceramics from sites in Brunei, south Philippines, Sarawak, and Johor Lama during the precolonial period (AD 700–1500) (Bellwood and Omar 1980). Significantly, Bellwood and Omar (1980: 173) have argued that "the distribution pattern [of 'Tanjong Kubor' ware] is related to the development of the Malay language as a trading language in those areas where it is most commonly spoken today."

Back in Mainland Southeast Asia, the "sudden" appearance of pottery decorated using incised and impressed techniques, alongside rice and millet cultivation, domesticated dogs and pigs, small polished stone tools, stone or shell bracelets, bead necklaces, textiles made from spinning yarn with spindle whorls and a mortuary ritual involving extended burials, led archaeologists to hypothesize that this "Neolithic cultural package" represents the expansion of agricultural communities from Southern China into the region (Higham 2014: 103; Rispoli 2007: 235–243). Just like Solheim's "Sa-Huynh-Kalanay" and "Bau-Malay" pottery traditions in Island Southeast Asia, "incised and impressed earthenware" are primarily defined by the decorations they bear which Rispoli characterizes as a "finite repertory of designs" made by incised and impressed techniques (Rispoli 2007: 235–236). While the "incised and impressed" tradition flourished during the "Neolithic" (c. 2000–1000 BC), it did not appear to survive past the subsequent "Bronze" (c. 1000–500 BC) and "Iron" Ages (c. 500 BC–AD 500) in Mainland Southeast Asia, whereas older decorative techniques – especially cord and carved paddle-marking as well as burnishing – persisted alongside the emergence of new subregional decorative techniques, vessel forms (Solheim II 2003: 17–18; White and Eyre 2010: 67), and more importantly, *chaînes opératoires*.

The ceramic tradition at the prehistoric site of Ban Chiang embodies this stylistic transition from the "Neolithic" to the "Metal" Ages in Mainland Southeast Asia. A long mortuary sequence at the site located in the Sakorn Nakhon Basin of the Khorat Plateau in Northeast Thailand revealed the use of ceramic artifacts as part the mortuary assemblage across three broad periods in succession: "Early" (c. 1600–505 BC), "Middle" (c. 760–200 BC), and "Late" (c. 200 BC–AD 200) (Higham et al. 2015: 7–10; White 2008). During the "Early Period" covering the "Neolithic" and early to middle "Bronze Age," complete globular or beaker ceramic vessels decorated with "densely incised designs" and cord-markings were placed near the head or feet of flexed, crouched, or extended adult burials, whereas fetuses and infants were interred within similarly decorated jars (Labbé 1985: 51–52; White 1982: 20, 23–25). By the "Middle Period" or late "Bronze" to early "Iron" Ages however, changes in mortuary rituals saw the interment of only extended adult and child burials mostly above, but sometimes also below, a layer of fragmented ceramic sherds from one to as many as 11 individual vessels (Labbé 1985: 52; White 1982: 20, 25–27). Painting was adopted as a new decorative technique and applied together with incised decorations alongside new vessel forms that included carinated and white-bodied vessels (Labbé 1985: 52; White 1982: 20, 25–27). At the onset of the "Late Period" or mid to late "Iron Age," the extended burial practice persisted but the mortuary ritual involving ceramic goods reverted to the "Early Period" practice of interring complete vessels, albeit directly above the body instead of around it (Labbé 1985: 52; White 1982: 20–28). The "classic" and internationally renowned "red-on-buff" painted Ban Chiang ceramic vessels emerges during this period, along with other vessels including red-fired

vessels with painted red decorations as well as red-fired burnished vessels; cord-marking is also identified on ceramics across both "Middle" and "Late Period" ceramic vessels (Labbé 1985: 52).

The decorative and surface treatment technique of burnishing becomes a hallmark of another significant prehistoric ceramic tradition: "Phimai Black." Identified and described by Solheim in 1965, "Phimai Black" ceramics are earthenware ceramics that were produced during the "Iron Age" in the Phimai region of the upper Mun River valley of the Khorat Plateau (Welch 1985: 194). The diagnostic features of the "Phimai Black" are twofold: a range of geometric or curvilinear streak-burnishing patterns of a dull to bright lustre set upon a grey to black surface color achieved from reduction firing (Welch 1985: 195–197). A wide range of vessel forms appear to constitute the "Phimai Black," but ovaloid jars and bowls are the supposed archetypes of this tradition. Significantly, it is hypothesized that the "Phimai Black" constitutes part of a wider, cultural horizon of reduced-fired and pattern-burnished ceramic production that encompassed the Mekong delta, northern Cambodia, as well as northeast and central Thailand during the Iron Age (Fehrenbach 2009: 134–135). Reduced-fired "blackware" pottery have also been recovered from the "Early Period" stratums at Ban Chiang, but are typically decorated with incised and cord-marked patterns reminiscent of – if not descended from – the "Neolithic" "incised and impressed" tradition (Labbé 1985: 55–56). The recent discovery of small circular updraft ceramic kilns associated with supposedly "Phimai Black" vessels at the late "Iron Age" site of Non Ban Jak in the Phimai region (Higham et al. 2014: 9, 31–33) not only supports the hypothesis of higher firing temperatures (than the average prehistoric earthenware vessel) involved in their production but also heralds a significant change in the *chaînes opératoires* of Southeast Asian ceramic production in the centuries to come.

High-Fired Stoneware and Porcelaneous Glazed Ceramics in Southeast Asia

In spite of the development of wheel-throwing and kiln-firing techniques during the historical period in Southeast Asia, local potters did not manage to produce true porcelain, an accomplishment which required a specific set of raw materials and techniques that was solely achieved by the Chinese during the Tang dynasty (AD 618–906) (Kingery and Vandiver 1986: 10). Nonetheless, potters in various parts of Mainland Southeast Asia eventually managed to achieve firing temperatures high-enough to produce both unglazed and porcelaneous glazed stoneware ceramic artifacts. While small circular, updraft kilns may have been an autochthonous innovation, it has been hypothesized that the larger, high-temperature cross-draft stoneware kilns during the historic period in Southeast Asia were derived from two separate sources from China (Hein 2008), where stoneware ceramics have been produced as early as the Shang Dynasty (c. 1027–771 BC) (Kingery and Vandiver 1986: 10).

Vietnamese Ceramics

Having had a long history of political and cultural interactions with the Chinese beginning as early as 111 BC, the Vietnamese started to produce high-fired ceramics as early as the second century AD at the high temperate kiln complex of Tam Tho in Thanh Hóa province (Hein 2008: 13–14). At the same time, a variety of glazes began to be applied on the surfaces of these high-fired ceramics which included "thin whitish glaze" and "glassy-green ash-glaze drips" (Stevenson 1997: 28–29). Developments in the Vietnamese ceramic tradition remains unclear in the intervening centuries until the Lý (AD 1009–1225) and Trần (AD 1225–1400) dynasties where Vietnamese potters produced a "happy anarchy" of ceramics by localizing the shapes, glazes, and decorative motifs of Chinese vessels in an original manner (Stevenson 1997: 30–31). Ceramics typically produced during the Lý and Trần dynasties include jars, beakers, bowls, and ewers with an assortment of decorations such as incised or moulded friezes of animals, plants, and human figures as well as zoomorphic spouts (Stevenson 1997: 32–33). "Ivory-colored" ash glazing is characteristically applied to Lý ceramics, whereas Trần ceramics usually bore green glazing due to its higher iron content (Stevenson 1997: 34).

Other types of monochrome glazing that occurred during the Lý–Trần period included variations of the green "celadon" glaze ranging between yellow to olive colors, dark "apple-green" glaze composed of copper oxides within a lead flux as well as a brown iron-oxide glaze (Stevenson 1997: 34). Polychrome ceramics bearing a brown and ivory-colored glazing on the exterior and interior surfaces, respectively, are also a distinctive typology produced by Vietnamese kilns during the thirteenth and fourteenth centuries AD (Stevenson 1997: 34).

Following the development of white-bodied ceramics bearing underglaze cobalt blue decorations at the Jingdezhen (景德镇 Jǐng Dé Zhèn) kilns in China during the fourteenth century AD, Vietnamese potters began to produce Blue-and-White ceramics sometime towards the late Trần period as well (Bùi 2001: 137). Vessels that were produced included bowls, dishes, jarlets, vases, and ewers featuring decorations inspired by Chinese designs and motifs such as chrysanthemum and peony flowers, vegetal scrolls, lotus leaves, bamboo, as well as animals and mythical creatures such as fish and lions, dragons and phoenixes (Bùi 2001: 138–142). Glazes commonly applied on the Blue-and-White ceramics during this period include light blue, greyish white, and ivory white colors (Bùi 2001: 138). Four to five spur marks can typically be seen on the unglazed bases of these vessels indicating the use of stacking supports between vessels during the kiln-firing process in this period (Bùi 2001: 138).

By the fifteenth century AD, an "explosion" of new vessel forms and decorations saw the production of basins, large vases, bottles, stem cups, small bowls, zoomorphic and fruit-shaped ewers, covered boxes, *kendis,* as well as non-vessel artifacts such as human statues and tiles (Bùi 2001: 143–145). Glazes applied on ceramics during this period are generally clear and glossy, but appear white, bluish white, or opaque white as they lie above a layer of slip on the ceramic surface (Bùi 2001: 148). The presence of unglazed rings on the bases and feet as well as rims indicates a shift to the direct stacking of vessels during kiln-firing from the use of kiln supports characteristic of the fourteenth century (Bùi 2001: 148). The renowned Blue-and-White globular vase on display at the Topkapı Palace Museum in Istanbul, Turkey, is a product of the Chu Dau kiln complex in the Nam Sách district of North Vietnam during this time (Miksic 2009a: 59–60). Vietnamese potters also made overglaze polychrome ceramics with decorations painted in red, green, and yellow enamel colors at this time, but these ceramics appears to be produced solely for export as they were mostly recovered outside of the country (Stevenson 1997: 38).

In spite of the political turmoil and civil unrest during the Lê (AD 1428–1788) and Mạc (AD 1527–1677) dynasties, Blue-and-White ceramics continued to be produced by Vietnamese kilns through the sixteenth century AD. Although new vessel forms such as the large water basins, planters with three kneeling legs as well as high-footed bowls and dishes with equally ornate underglaze cobalt blue painted decorations emerged, it was observed that some fifteenth century forms such as the *kendi* and covered boxes had abruptly ceased production as well (Bùi 2001: 149–150). Landscape paintings featuring uncluttered compositions of humans, animals, and scenery emerged as a new style of decoration for Blue-and-White ceramics in this time (Bùi 2001: 150). With a few exceptions such as the Bát Tràng kiln complex near Hanoi, the production of Vietnamese ceramics went into decline by the seventeenth century AD in spite of local economic growth in Vietnam and the development of international maritime trade and relations between Europe and Southeast Asia at that time (Bùi 2001: 153; Stevenson 1997: 40). Blue-and-White ceramics, in particular, suffered a deterioration in both "technical and decorative" aspects (Bùi 2001: 153) in the face of mass-produced Chinese ceramics of relatively higher quality. The lifting of maritime trade restrictions by the Chinese Ming Dynasty (AD 1368–1644) leading to the re-entry of exported Chinese ceramics into Southeast Asia, and its concomitant imposition by the Lê dynasty and its successors the Trịnh (AD 1545–1787 AD) and Nguyễn (AD 1558–1777) lords is likely to have contributed to the decline of the Vietnamese ceramic industry by the eighteenth century AD (Stevenson 1997: 39–40).

Cham Ceramics

Prior to the southward expansion of Vietnamese culture and polities from the Red River Delta, an ethno-linguistic group of Chamic speakers belonging to the Austronesian language family distinct from their Austroasiatic ethno-linguistic Vietic and Mon-Khmer neighbors to the north and south, respectively, resided along the coasts of present-day central Vietnam (Vickery 2009: 45). Occupying the same region previously held by the late "Iron Age" "Sa-Huynh" archaeological culture in prehistoric times, the Chamic peoples established a series of Indianized urban centers and polities along the central coast between the second and eighth centuries AD at various sites including Trà Kiệu, Mỹ Sơn, Đồng Dương, Pô Nagar, Pô Klaung Garai, Pô Rômê, and Quy Nhơn (Vickery 2009: 46–48). Collectively known as "Champa," the tides and fortunes of these polities waxed and waned through the centuries until their eventual conquest by the Vietnamese in the seventeenth century AD (Vickery 2009: 46–57).

The earliest high-fired Cham ceramic kilns discovered to date are located at the Gò Sành kiln complex in Bình Định province – then under the control of the Cham polity of Vijaya (c. twelfthy–fifteenth centuries AD) – where production is estimated to have occurred between the fourteenth and fifteenth centuries AD (Miksic 2009a: 61). At least four other Vijayan kiln complexes have been identified within Bình Định: Gò Hời, Gò Ké, Cây Me, and Trường Cửu (Diem 2011: 209). A wide range of ceramic vessels including dishes, bowls, basins, cups, bottles, *kendis*, pots, and jars were produced at the kilns of Bình Định (Diem 2011: 210). Glazes that are commonly applied included brown, green, and grey colors (Brown 1988: 37; Diem 2011: 210). Developments in kiln-firing techniques parallel to that of Vietnamese kilns in the north also saw the shift from indirect stacking to a *chaîne opératoire* involving the direct stacking of vessels on unglazed rims and bases at the Gò Sành kiln complex (Diem 2011: 211).

Lao Ceramics

The earliest high-fired ceramic kilns discovered in Laos to date belong to the kiln complex located at the village of Ban Mae Tao Hai – also known as Si Sattanak – 3 km east of Vientiane (Brown 1988: 94; Hein 2008: 24–25). The presence of associated Chinese Blue-and-White ceramics assigns a relative *terminus post quem* date of 1563 AD to the kiln complex (Brown 1988: 95; Hein 2008: 24). Ceramics produced at the Ban Mae Tao Hai complex included jars, bowls, cups, oil lamps, *kendis*, roof finials, as well as both tobacco pipes and bowls (Brown 1988: 94; Hein 2008: 24). Only one type of glazing – a "thin, translucent greenish" ash glaze which was applied over a white slip – has been identified at the complex (Brown 1988: 94; Hein 2008: 24). Vessels with this thin green glaze sometimes have underglaze decorations of circles or dots as well (Brown 1988: 94).

Two more kiln complexes have been identified since the initial discovery of the Ban Mae Tao Hai complex in 1970. The first complex comprising of at least 20 kilns have been identified at Ban Xang Hai along the banks of the Mekong River about 20 km north of Luang Prabang (Hein 2008: 23). Ceramic artifacts produced at this site primarily consist of unglazed bowls, jars bearing incised and appliqué decorations, mortars, fishnet weights, spindle whorls, plum bobs, and even animal figurines (Hein 2008: 24). The remains of another kiln complex at a village – also named Ban Tao Hai ("Village of Jar Kilns") – near Luang Prabang has also been reported in recent years (Hein 2008: 24). Ceramics produced in this village include a range of unglazed grey jars as well as architectural roof tiles and finials, while a number of green-glazed ceramics bearing impressed geometric and animal decorations have also been found on the surface of the site (Hein 2008: 24).

Khmer Ceramics

High-fired ceramics are traditionally thought to be produced by the Khmers when they established the Indianized kingdom of Angkor (c. ninth–fifteenth centuries AD) on the Kulen Plateau next to the floodplains of the great Tonlé Sap lake sometime during the ninth century AD. Aside from the hypothesized Chinese origins of Khmer kilns (Hein 2008: 16–17), it has been observed that high-fired Khmer ceramics share many similarities with contemporaneous products from the Xicun (西村 Xī Cūn) and Chao-an (潮安

Cháo Ān) kilns in the southern Chinese province of Guangdong (广东 Guǎng Dōng) (Brown 1989). Nevertheless, Khmer ceramics exhibited far less Chinese influences than their Vietnamese counterparts, and eventually developed into the "most un-Chinese-like" ceramic tradition in Southeast Asia (Brown 1988: 42).

The earliest high-fired glazed ceramics recovered to date were found at present-day Roluos, the site of Hariharalaya, the first capital of the Angkorian kingdom, in the form of green-glazed tiles and stoneware vessels during the reign of Indravarman I (c. AD 877–899) (Brown 1988: 42). Wasters of similar ceramics located at the Thnal Mrech kiln complex located on Phnom Kulen to the north of Roluos suggests that these early Khmer ceramics were produced at that site (Brown 1988: 43). Firing supports in the form of "sausage-like" coils, semi-cylindrical supports, and small balls of clay were used to stack vessels indirectly during firing (Miksic 2009a: 54). The oldest kiln complex to date, however, is located at the site of Bang Kong in the vicinity of Roluos where one of 39 identified kilns have returned a calibrated radiocarbon date ranging between AD 893–985 (Miksic 2009a: 54). Green-glazed ceramics produced at Bang Kong, however, were observed to be made of a higher quality clay, glaze, and firing technique than those fired at the Thnal Mrech kiln complex (Miksic 2009a: 54). Green-glazed vessels produced in this period includes forms such as bottles, small covered boxes, and bowls, which bear a variety of incised, carved, and moulded decorations and, in some cases, the mark of their potters on the exterior base surfaces (Brown 1988: 51). Other kiln complexes located near Hariharalaya and later, the great Khmer city of Angkor, that are known to produce green-glazed ceramics include Tani, Sarsey, and Khnar Po (Miksic 2009a: 54).

Another type of Khmer ceramic – "*Lie de Vin*" (named by French archaeologist Bernard-Philippe Groslier after their resemblance in surface color to that of the residue left in old wine bottles) – began to be produced sometime during the tenth century AD (Brown 1988: 44–51). *Lie de Vin* vessels are not strictly "glazed" per se, as the dark reddish-purple color usually permeates the clay body as well; where "glazing" occurs, it only appears as a very thin slip or "gloss" (Brown 1988: 44). Pending further research on the subject, it is more likely that *Lie de Vin* "glaze" is a result of intrinsic chemical processes between the clay body, fuel combustion, and the firing atmosphere as opposed to a deliberate application of glaze on the vessel by the potters themselves. The provenance of *Lie de Vin* ceramics also remains unknown as the kilns producing these ceramics have yet to be found. *Lie de Vin* vessels typically consist of large basins and jars bearing a mixture of carved, incised, and combed decorations (Brown 1988: 44).

Production of both green-glazed and *Lie de Vin* ceramics continued unabated until sometime between the tenth and eleventh centuries when a new type of Khmer ceramic – brown-glazed vessels – emerged into the market (Brown 1988: 51–52; Miksic 2009a: 55). The best-known examples of Khmer brown-glazed ceramics are the large "baluster vases" produced by the Angkorian kilns located in Buriram province of present-day Thailand (Miksic 2009a: 55). More than 200 individual kilns alone were identified by the archaeologists of the Thai Fine Arts Department by the 1980s in the province, while hundreds more have reportedly been destroyed by various agricultural and deforestation activities (Brown 1988: 45–46). Aside from the baluster vases, other brown-glazed vessel forms includes basins, jars, pots, and bottles (Brown 1988: 51–52). Brown-glazed ceramics were also produced at the Thnal Mrech kiln complex as well as at various kiln sites located along the Angkorian highways – such as Ban Kruat and Teap Chei – that emanated from the Angkorian heartland out towards the outer provinces of the empire (Miksic 2009a: 54). While *Lie de Vin* vessels appears to have ceased production after the proliferation of brown-glaze vessels during the eleventh century AD, green-glazed ceramics continued to be produced, albeit in smaller quantities, alongside brown-glazed ceramics up to the thirteenth century AD (Brown 1988: 52–53). New forms of Khmer ceramics that emerged at this time includes green and brown-glazed vessels and zoomorphic lime pots (Brown 1988: 52–53).

It is hitherto unclear what happened to the Angkorian ceramic industry after the thirteenth century AD due to the lack of archaeological evidence (Miksic 2009a: 55). As the Angkorian empire declined in the face of invasions by the Siamese and Cham and the capital shifted away from the Tonle Sap floodplains towards the south further down the Mekong River, activity at the aforementioned kilns appears to have all but ceased (Brown 1988: 53). Aside from the waning fortunes of the empire, the demise of the Angkorian ceramic industry may also be expedited by the influx of mass-produced ceramics from the provincial kilns of southern China into the region (Brown 1988: 54). The recent discovery of large stoneware jars used at various jar burial rock shelter and cave sites on the Cardamom Mountains to the south, however, suggests the continuation of the craft up to the fifteenth century AD as they were found in association with Chinese and Thai ceramics from the same period (Miksic 2009a: 56).

Thai Ceramics

The origins of Thai high-fired ceramics and kilns are as hazy as that of the decline of their counterparts in neighboring Angkor. The rise of the Tai principalities – especially that of Sukhothai – in present-day Thailand between the thirteenth and fourteenth centuries AD saw the emergence of the best-known, if not earliest, high-fired kiln complexes at the sites of Sawankhalok and Si Satchanalai (previously called "Chalieng") (Brown 1988: 57, 61–62). Although Thai folklore attributes high-fired ceramic and kiln technologies to the arrival of Chinese potters in Sukhothai (Miksic 2009a: 62), archaeological research have demonstrated that both technologies have largely evolved autochthonously while receiving external stylistic influences which lead to the introduction of white clay, underglaze iron black painted decorations and green glazing (Hein 2008: 11–12). The excavation of eleven kilns at the site of Ban Kao Noi near the old Sukhothai city of Si Satchanalai have also revealed evidence of an even earlier phase of low-fired, lead-glazed ceramic production which has been attributed to the Mon, an ethnolinguistic group that preceded the Tais in present-day Thailand (Brown 1988: 62–63).

The earliest, pre-Sukhothai, high-fired glazed Sawankhalok wares were "transitional" (as they were found in association with "Mon" ceramics) underglaze iron black dishes and plates bearing the characteristic stylized fish and flower painted motifs on the interior vessel wall and base surfaces (Brown 1988: 63). These underglaze decorations are also observed to be more formalized and "stilted," more "intricate and complex" than those of the Sukhothai period (Brown 1988: 64). Glazes of these "transitional" wares range from clear to "slightly cloudy" with a bluish or greenish color (Brown 1988: 65).

Ceramic production at Sawankhalok kilns became more varied during the early Sukhothai period (c. thirteenth–fourteenth centuries AD). Aside from the continued production of underglazed iron black and brown decorated plates and bowls, other types of Sukhothai ceramics include undecorated monochrome creamish-white slip with clear glaze, unglazed stoneware vessels such as storage jars and basins as well as unglazed earthenware vessels including *kendis* (Brown 1988: 67, 70). Early Sukhothai plates and bowls also had spur marks on the interior base surfaces as they were stacked upon each other through the use of disc-shaped supports during the firing process (Brown 1988: 69). The entire stack of ceramics, in turn, was placed on top of a tubular support that leaves a characteristic "blackish circular scar" on the exterior base surface of the lowest dish or plate (Brown 1988: 69).

A greater variety of ceramics were produced from the middle to late Sukhothai period (c. fourteenth–sixteenth centuries AD), the most notable being the classic "celadon" (green-glazed) ceramic plates and dishes as well as bowls, bottles, jars, jarlets, figurines, and *kendis* (Brown 1988: 65–66). Other new types and forms of ceramics produced in this period includes underglaze iron black-covered boxes, brown-glazed figurines, "Brown-and-Pearl" ceramic architectural fixtures with inlaid white incised decoration, opaque matt-white glazed ceramics, and architectural fixtures, black-glazed storage jars, bottles, and roof finials and small olive-glazed jars and

jarlets (Brown 1988: 70–71). Unglazed stoneware mortars, baluster jars, and basins as well as high-fired earthenware *kendis* continued to be produced in this period as well (Brown 1988: 71).

The discovery of other kiln sites aside from the Sukhothai kiln complexes revealed the production of other contemporaneous Tai high-fired ceramics sometime between the thirteenth and fifteenth centuries AD (Brown 1988: 82). These kiln complexes include Kalong, Sankampaeng, Phayao, Phan, Wang Nua Lampang, San Sai, Nan, Khun Yuam-Mae Hong Son in northern Thailand, Pitsanulok, Nakorn Thai and Pitchit in north-central Thailand, as well as Singburi and Supanburi in central Thailand (Brown 1988: 81–96).

Ceramics in Myanmar

The development of high-fired glazed ceramic and kiln technology in present-day Myanmar remains the least understood high-fired pottery tradition in Southeast Asia. Early twentieth-century research on the subject documented the contemporaneous existence of various types of green lead and wood ash-glazed ceramics across various parts of the country (Brown 1988: 104). While lead-glazed earthenware ceramics were being produced by kilns and used as architectural fittings and bricks as early as the ninth century AD (Hein 2008: 18), the earliest and best-known high-fired ceramics produced from this region to date remains large brown-glazed stoneware storage jars eponymously named "Martaban" (or "Martavan") after the port and sister city of Pegu between the thirteenth and fourteenth centuries AD (Brown 1988: 103). The records of the famous fourteenth century AD Moroccan scholar and traveller Ibn Battuta and subsequent Europeans who visited this part of the world mentioned the initial use of these "Martaban" jars as storage vessels for various trade goods – such as pepper, preserved fruit and opium – and were themselves shipped as trade goods in their own right (Brown 1988: 101; Miksic 2009a: 66). The specific kilns producing these famous stoneware vessels, however, have yet to be found or identified to date, though it has been hypothesized that they may have been produced at the kiln complex in the neighboring region of Twante (Brown 1988: 103; Hein 2008: 21).

Pending further research into the subject, it is estimated that the high-fired kilns and ceramics of the lower Irrawaddy region date approximately to the fifteenth century AD (Miksic 2009a: 67). Recent research at the Twante kiln complex have revealed "hundreds of brick-built surface crossdraft kilns" (Hein 2008: 19) that largely produce green-glazed "celadons" in the form of plates, bowls, zoomorphic figurines, as well as jarlets, double gourd vessels, and wall tiles (Miksic 2009a: 67). Brown-glazed as well as "Green-and-White" ceramics have also been recovered at these kiln sites, albeit in smaller quantities (Miksic 2009a: 67). Green-and-White ceramics are thought to be produced by the application of a green paint above a "milky opaque white" lead glaze which, upon firing, sinks into the glaze (Brown 1988: 103). White-glazed monochrome ceramics have also been recovered from various Tak or Omkoi burial sites located in the border region between Thailand and Myanmar (Brown 1988), but their precise provenance remains as elusive as the rest of the high-fired glazed ceramics in the country to date.

Traditional Chinese Kilns in Southeast Asia

During the early twentieth century, several groups of Chinese potters from various provinces in southern China such as Fujian (福建 Fú Jiàn) and Guangxi (广西, Guǎngxī) were known to have migrated into and established ceramic kiln in various parts of Southeast Asia including Vietnam and Cambodia (Miksic 2009a: 69) as part of the wider Chinese diaspora into various European colonies around the world. The products of these Southeast Asian-Chinese kilns included utilitarian ceramic dishes and bowls decorated with underglaze cobalt blue and overglaze polychrome enamel motifs, ornamental and architectural finishing and reportedly even porcelain in "Qingbai" glaze (青白, Qīng Bái) and underglaze blue decoration (Miksic 2009a: 69). Little else is known of these Southeast Asian-Chinese kilns and the topic warrants further research in the future (Miksic 2009a: 69).

Key Issues

The Origin of Southeast Asian Ceramics

Given the early Holocene appearance of ceramics within a seemingly hunter-gatherer milieu characterized by the "Hoabinhian" and other similar stone tool industries, it has been observed that the appearance of ceramics in Southeast do not seem to correlate with either social or demographic changes typically accompanying their invention (or introduction) in the "Old World" (Miksic 2003b: xix; Zeitoun et al. 2012: 530). As these early ceramic artifacts are also often recovered alongside flaked and ground stone artifacts across many prehistoric sites in the region (Bronson and White 1992a: 496), it has also been observed that the technique of grinding and polishing working surfaces on stone tools had occurred together with the development of ceramic technology at many "Hoabinhian" sites across Mainland Southeast Asia (Higham 2014: 55). Significantly, this trajectory of development in ceramic technology in the region appears to follow that experienced by the rest of East Asia, where pottery production has been found to "predate sedentism, cultivating cereals, and producing polished stone axes or adzes" (Cohen 2013; Cohen et al. 2017: 36; Jordan and Zvelebil 2009: 39–45). More importantly, these Palaeolithic dates for ceramic technology firmly decouples pottery production from the "Neolithic" paradigm as proposed by Childe (1936) in both East and Southeast Asia (Cohen et al. 2017; Gibbs and Jordan 2016; Jordan and Zvelebil 2009: 33–39).

Open and Kiln-Firing in Southeast Asia

Not only do the circular updraft kilns at Non Ban Jak represent the earliest evidence of kiln technology found within a firm "Iron Age" context to date, they also highlight a shift in the firing of earthenware ceramics from using an open bonfire during the late Holocene through the "Neolithic" and "Bronze" Ages to kiln-firing in the "Iron Age." What remains to be understood, however, is whether the prehistoric kilns at Non Ban Jak represent an autochthonous evolution in ceramic technology or technological transfer through cultural diffusion by means of trade and exchange. While the dynamics of regional and long-distance trade and exchange during the prehistoric period in Southeast Asia remains poorly understood to date, it is evident that trade and exchange was firmly established by the Iron Age due to the abundance of "exotic" goods that have been recovered from various sites across the region at that time (Higham 2014). In particular, recent research on prehistoric stone and glass beads as well as copper-based metal goods and imported ceramics from South Asia and Southern China recovered from these sites has demonstrated that intra-regional trade and exchange networks – which are, in turn, connected with extra-regional trading connections such as the South China Sea network and those with South Asia and the Roman world – have managed to redistribute these goods across various "Iron Age" sites in the region (Bellina and Glover 2004; Favereau and Bellina 2016).

Fine-Paste Ceramics in Southeast Asia

What is also evidently clear is that long-distance maritime trade and exchange during the turn of the millennium between Southeast Asia and the Indian subcontinent lead to the appearance of another significant ceramic tradition and cultural horizon: fine-paste earthenware ceramics and its most prolific typology, the "*kendi*" (Bellina and Glover 2004: 80; Miksic and Yap 1988–1989: 46). Fine-paste earthenware ceramics can be understood as artifacts made of clay with little to no sand-sized inclusions, resulting a relatively smooth (and in some cases, "soapy") surface texture on both exterior and interior surfaces (Miksic and Yap 1988–1989: 47). *Kendi* is a Malay term thought to be derived from "*kundika*," the Sanskrit word for smaller versions of the "*kundi*" (indicated by the diminutive suffix "*-k*"") which describes, in turn, "a pot with a spout" (Khoo 1991: 4). Fine-paste earthenware and the distinct morphology of the *kendi* form during the "Iron Age" represents an abrupt and distinctive break from prehistoric Southeast Asian earthenware *chaînes opératoires* since the advent of ceramic technology in this region. The *kendi* form, in particular, is a distinct morphology foreign to prehistoric Southeast Asia but strongly associated

with the Indian subcontinent and more importantly, Hindu-Buddhist culture where they were used as a ritual vessel for "sprinkling lustral water in Brahmanic or Buddhist ceremonies" (Khoo 1991: 4).

Wheel-Throwing in Southeast Asia

More importantly, the concomitant appearance of wheel-throwing alongside kilns during the late "Iron Age" and proto-historic period also heralds another significant change in the *chaînes opératoires* of Southeast Asian ceramic production. Hitherto, prehistoric ceramic vessels in the region were formed using a variety of hand moulding, coiling as well as paddle and anvil techniques, whereas the majority of fine-paste earthenware ceramics were formed using wheel-throwing. To date, the earliest evidence of wheel-throwing and kiln-firing remains that of a pivot for a potter's wheel and kiln supports at one the earliest Southeast Asian urban site of Óc Eo (c. AD 200–600) on the Mekong Delta by French archaeologist Louis Malleret in 1960 (Malleret 1960: XIX, LIV; Miksic 2003a: 21; Miksic and Goh 2017a: 163). The appearance of a completely new ceramic *chaîne opératoire* – characterized by the use of a fine-paste clay recipe, wheel-throwing and kiln-firing – at a center of the first Indianized polity known toponymically to the Chinese as "Funan" (扶南 Fú Nán) is indicative of both cultural and technological transfer and interaction between Southeast Asia, India, and China at this time. Based on these inferences, it has been concluded that "dual technological traditions" of ceramic manufacture emerged by the mid-first millennium AD on the Mekong Delta, characterized by an indigenous open-fired, paddle-and-anvil earthenware and a "newer, foreign tradition" involving fine-paste, wheel-thrown, and most likely kiln-fired earthenware ceramics (Stark 2003: 225).

Intra-Regional Maritime Trade in Southeast Asian Ceramics

More importantly, the archaeological record suggests that Southeast Asian potters were not only producing ceramic artifacts for domestic consumption but also appeared to be producing them for intra-regional trade and exchange as well. Between the ninth and sixteenth centuries AD, five distinct ceramic "interaction spheres" which saw the circulation of a variety of both Southeast Asian earthenware and stoneware ceramics within the region have been identified by Miksic and Goh (2017b). The first refers to the production of domestic earthenware pottery and not so much to the circulation of actual ceramic artifacts themselves but rather that of their *chaînes opératoires* as there appeared to be a "broad distribution of similar pottery over a wide area" (Miksic and Goh 2017b: 812). Nonetheless, the exchange of earthenware pottery between Malayo-Polynesians and Melanesians in eastern Indonesia and Papua New Guinea during ritual trading voyages called "*hiri*" observed in the nineteenth and early twentieth centuries (Miksic 2009b: 95) suggest that earthenware pottery may have been traded – albeit in a smaller scale – in the region as well, especially between communities within Island Southeast Asia which do not have the technology to produce high-fired, glazed stoneware ceramics like their mainland counterparts. The second sphere refers to the trade and exchange of fine-paste earthenware ceramics aforementioned, whereas the last three spheres refer to the trade and exchange of high-fired stoneware ceramics produced by the kilns of mainland Southeast Asia (Miksic and Goh 2017b: 814).

The intra-regional trade and exchange of Southeast Asian earthenware and stoneware ceramics is best represented by the ceramic cargos of two shipwrecks: the Intan and Cirebon. The Intan wreck is thought to be a Southeast Asian vessel which carried close to 8000 ceramic vessels when it sank south of the Bangka Strait sometime in the tenth century AD (Flecker 2009: 38). While half its ceramic cargo consists of Chinese stoneware and porcelain goods, the remainder comprises of hundreds of fine-paste earthenware bottles and kendis thought to have been produced by early Southeast Asian kilns located in present-day southern Thailand (Flecker 2009: 38; Miksic and Goh 2017b: 817). The Cirebon wreck, a Southeast Asian ship of lashed-lugged construction, was also found carrying earthenware jars and kendis that are likely to have a Southeast Asian

provenance amidst a large cargo of Chinese ceramics when it sank sometime between the tenth and eleventh centuries AD (Liebner 2014; Miksic and Goh 2017b: 817). During a period of shortage of Chinese ceramics precipitated by intermittent imperial restrictions on private maritime trade in the fifteenth century AD (commonly known as the "Ming Gap"), high-fired Thai, Vietnamese, Cham, and Burmese ceramics were found to have filled the void in the market as testified by the cargoes of shipwrecks recovered from this period (Brown 2009). These shipwrecks, such as the Rang Kwien which sank off the coast of Thailand, the Turiang off the eastern coast of peninsular Malaysia, the Pandanan wreck off the southern Palawan coasts in the Philippines and the Belanakan wreck off the coast of west Java in Indonesia collectively carried tens of thousands of mainland Southeast Asian ceramics and demonstrated the extent of their trade across the region (Brown 2009: 38–45).

Ceramics in Southeast Asian Culture

Aside from domestic consumption, Southeast Asian ceramics have long been used in both mortuary and religious rituals in the region. Ceramic vessels and artifacts began to be interred as part of the mortuary ritual not long after their appearance in the region, with the earliest evidence of this practice discovered at the Buang Bap cave complex in the Surat Thani Province of Thailand, where "cord-marked cups" were found interred with a burial reportedly dated to c. 5250 BP by Srisuchat and Srisuchat (1992). Thereafter, ceramics began to emerge as a common part of the mortuary assemblage in Southeast Asia throughout prehistory (Bellwood 2017; Higham 2014). With the arrival of Hinduism and Buddhism in the region during the late prehistoric and early historic periods, ceramics were adopted as part of various Hindu-Buddhist rituals as represented by the aforementioned adoption of fine-paste kendis as lustral vessels (Miksic 2009b: 97). Aside from kendis, other earthenware vessels are also likely to have been used in these ceremonies as seen in the recovery of "several hundred" vessels such as "large spherical water jars" and "abulation bottles" thought to be ritually damaged and buried at the pre-Angkorian city of Sambor Prei Kuk (Miksic 2009b: 96). The significance of ceramics in both sociocultural and religious spheres is also represented by a wide variety of non-utilitarian ceramic forms and artifacts including anthropomorphic and zoomorphic sculptures as well as elaborate architectural fittings such as roof finials and tiles which are usually high-fired and glazed stoneware ceramics (Rooney 2013: 15–17).

International Perspectives

Aside from the familiar tropes of its role in the Palaeolithic migration of humans from Asia into Australia, early agriculture and long-distance maritime exchange between the Mediterranean world, India, and China, the history and archaeology of Southeast Asia, let alone Southeast Asian ceramics, receive relatively little attention among the global academic community outside of the specialists in the field themselves. While there is some evidence of their circulation further afield across the Indian Ocean and South China Sea into sites in the Middle East and Japan (Miksic and Goh 2017b: 826–827), the nature and dynamics of the trade of Southeast Asian ceramics outside the region remains relatively understudied and unknown. Future research into the import and consumption of Southeast Asian ceramics at these international sites will undoubtedly reveal significant socioeconomic interactions between these regions and Southeast Asia and thereby, reinforce its position as the maritime crossroads of a globalized world.

Future Directions

Ceramic artifacts are ubiquitous throughout Southeast Asian archaeological sites, but archaeological research in Southeast Asian ceramics remains in its infancy compared to the study of these artifacts in art history. To date, the analysis of archaeological ceramics seldom exceeds their utility in reconstructing cultural histories

through typological classification as well as a supplementary – albeit useful – tool for intra- and inter-site chronological sequencing and relative dating. The study of Southeast Asian earthenware ceramics, in particular, has also been overshadowed by that of its more aesthetically attractive high-fired ceramic cousins. Although earthenware sherds make up the majority of artifacts recovered from archaeological sites in the region, they still remain "neglected in reported finds, analyses, and published references" (Rooney 1987: 1). At the same time, ethnographic records of traditional or rural earthenware potters remain few and sporadic (i.e. Cort and Lefferts Jr. 2010–2011; Stark 1991) because research is narrowly concentrated on selected Southeast Asian ceramics which are "recognized as having great cultural and monetary value, such as the famous prehistoric Ban Chiang pottery and the high-fired celadon wares of Sukhothai and Sawankhalok" (Shippen 2005: 11). Consequently, any identification and analysis of earthenware ceramics can only rely on comparisons with the few existing published catalogues and be informed by the existing archaeological record and historical context that surrounds these artifacts.

The potential and importance of ceramics in understanding socio-economic and political organization in Southeast Asia also remains overshadowed by the structural and monumental remains found across the region, and the pervasiveness of historical narratives reconstructed from epigraphic and textual sources. Consequently, archaeological research in the social organization of these historic polities remains generally oriented towards the study of major orthogenetic precolonial urban centers largely defined by the presence of architectural, statuary, and epigraphic remains (Miksic 2000). Conversely, there are relatively few archaeological studies of material cultural remains and their crucial role in the dynamics behind "evolving wealth differentials and social stratification" in prehistoric and early historic period societies (Junker 1999: 151).

The lack of research dedicated to the archaeological study of Southeast Asian earthenware was still endemic in the region as late as 2003 (Miksic 2003b). In an effort to remedy the situation and create a regional archaeological framework of earthenware analysis, Miksic's (2003) seminal study *Earthenware in Southeast Asia* encompassed the latest earthenware research across the major Southeast Asian nations. To date, it remains not only the sole publication that focuses solely on earthenware ceramics in Southeast Asia but also the only attempt to understand the development of the technology its use within a regional framework.

Nonetheless, the efforts of archaeologists over the last few decades have produced considerable – albeit disparate – data and literature on archaeological ceramics that have advanced the knowledge of socioeconomic, trade, and settlement patterns of precolonial societies in both mainland and island Southeast Asia. In particular, ceramic research has demonstrated that greater socioeconomic and political complexity in precolonial Southeast Asian societies is typically accompanied by the development of a "political economy" where certain goods function as a "material fund of power" which is used to "reinforce social inequality and political authority," with hereditary "elites" controlling the specialized production and exchange of such goods (Junker 1994: 3). Ceramics were often used in precolonial Southeast Asia as a measure and indicator of social rank distinction. Stylistic, technological, and distribution analyses of decorative earthenware pottery found in the Philippines have also suggested that some decorative styles could have been iconographic representations of inter-chiefly elite alliances or shared identity in the late prehistoric and proto-historic period (Bacus 2003). While much more remains to be done, the potential of ceramic artifacts in revealing more answers to our human past is slowly coming to the fore in Southeast Asian Archaeology.

Southeast Europe: Archaeological Museums

Eleni Kotjabopoulou
Archaeological Institute for Epirotic Studies, Ioannina, Greece

Introduction

The establishment of archaeological museums in Southeast Europe is tightly interwoven with the modern, often turbulent, political history of this highly diverse territory, its people, and cultural traditions. The gradual dissolution of the Ottoman Empire through the nineteenth to the early twentieth century and the creation of independent nation-states throughout the Balkan Peninsula (Hobsbawm 1990) – an ongoing process marked in a most traumatic way in the 1990s by the breakup of the former Yugoslavia – inevitably meant that deep history was conceptualized and interpreted in a linear, evolutionary, effectively nationalist perspective. The past, discontinuous and fragmented as it was, was nonetheless put on a high pedestal, as in many other parts of Europe, to be glorified and broadcast as an

"entity." This "pure", "innocent" and "protected" image of the past served legitimize and negotiate various, often conflicting, goals and aspirations (e.g., territorial, political, ideological and aesthetical) of the present.

Definition

Archaeological museums in Southeast Europe to a large extent still maintain the focus on artifact-centered, art history, "idealist" narratives, and only recently, since the late 1990s, did some of them begin to explore a different trajectory: one, which departs from the doctrine of proving, confirming or propagating historical continuity, "uniqueness" or remoteness. A reformed scope, admittedly of disparate pace and ideological tendency depending on the country or tradition in question, is emerging which attempts to bring to the forefront the *variability* of past cultural formations, the circumstances and the contingencies of particular socioeconomic contexts and processes and one, that seeks to give room to the *agents or actors* of history, the ancient people, their communities, ideologies, institutions, technologies, etc. However, despite this newer trend, archaeological museums in the Balkans continue to hold the lion's share in the domain of mainstream, top-down, identity-building. Nevertheless, some recent exhibitions explored evolving critical reevaluations and/or redefinitions of the past and a number of them have received international recognition.

Key Issues/Current Debates/Future Directions/Examples

The *singular* past rationale was, and to some extent still is, nowhere better exemplified than in the case of Greek archaeological and museum displays (Hamilakis 2007; Damaskos and Plantzos 2008). Not least, and this needs to be highlighted, because Classical ruins, especially *white* – yet initially polychrome-painted – marbled architecture and sculpture, not only served as the foundations *par excellence* of Hellenism, but equally, if not even more so as a fundamental image of European identity since the Enlightenment (Settis 2006). However, in a country which is an overwhelming palimpsest of ancient relics, curated at no fewer than 150 museums, the way has been opened to more public-oriented and democratic museum scenarios and practices. Put in other words, the intention is widespread – yet not fully implemented – to break with the tradition of repository-type exhibitions useful only to the *élite* "experts" and pleasing to educated aesthetes. No doubt, the recent influx of European Union support funds for carrying out extensive renovation and re-exhibition projects has greatly contributed to this trend as well as the *loss of innocence* of Greek archaeological theory and museology (Kotsakis 1991; Mouliou 2008). Interestingly, this wave of reform was initiated by two state-run museums not having as a subject matter the "golden" Classical past, but, instead, the somewhat less esteemed and specialized religious art history of the Byzantine (medieval) epoch. The Museum of Byzantine Culture, Thessaloniki, and its annex, the White Tower Museum, which hosts a multimedia enhanced itinerary into the multicultural, cosmopolitan history of that city, the second largest in the country, and the Byzantine and Christian Museum, Athens, constitute groundbreaking, open-minded interpretative exhibitions. In these, ancient peoples and their beliefs are center stage. Thematically instead of being taxonomically organized (Fig. 1), these displays offer sharp insights on long established national historiographies (Gazi 2011). In the last decade or so, among the many rearranged and refurbished and greatly improved regional Greek museums dedicated to antiquity, the Ioannina Archaeological Museum, Northwestern Greece, stands out for its cutting-edge, dialectical approach and appropriate design. In it, material cultural remains, whether of semi-nomadic mountain shepherds or of pilgrims to the oldest oracle site of Greece, that of Zeus (Jupiter) at Dodona, are used as vehicles, and not as self-evident, axiomatic values (artistic, technological or other) for the visitors to explore a multilayered past (Fig. 2) and to question *how* the past relates to the present and vice versa. This issue is most challenging for museums worldwide: it is an

issue which touches on various aspects of epistemology as much as of museography, and one which has not been adequately addressed in the recently opened (2009), heavily visited New Acropolis Museum, Athens. Some of the textbook masterpieces of ancient Greek art production – notably votive statues in which the historically contingent anthropocentric spirit of fifth century BCE democracy was encoded – are now housed in an imposing glass-and-concrete building, albeit elegantly emplaced in direct visual contact with the Athenian sacred hilltop (Fig. 3). Even though the exhibits remain largely un-contextualized (Plantzos 2011), the juxtaposition of the few *original* Parthenon friezes – which escaped Lord Elgin's dismantling project – with *plaster copies* from those on display at the British Museum (London), the Louvre (Paris) and elsewhere, do, however, make an eloquently strong, constructive argument in the debate on the

Southeast Europe: Archaeological Museums, Fig. 3 Exterior view of The New Acropolis Museum, Athens, Greece. In the background (*right*), the Acropolis hill and the Parthenon. (Photo by C. Economides)

repatriation and illicit circulation of antiquities internationally.

In the rest of the Balkan countries which experienced the former so-called eastern-bloc (communist) regimes, collections of antiquities, whether national or regional, have as a rule formed part of what can be called *diachronic* knowledge building institutions, focusing on the construction and legitimization of national/ethnic identities and visions. In Bulgaria, Rumania, and other new nation-states, relics of antiquity formed part of an "evolutionary" heritage continuum; until recently, in many cases, they were displayed under the same roof as artifacts from medieval times and ethnographic, cartographic, miscellaneous collections, even including those of natural history specimens, in the model of analogous nineteenth century central European establishments (e.g., Guzin Lukic 2011; Lozic 2011; Vukov 2011). In spite of the grave financial and other structural problems currently faced by these countries, some attempts are being made to review form, content, and layout. Site-specific archaeology museums stand at the forefront of this trend, which directs great emphasis on the educational aspect. A most informative case, the Krapina Neanderthal Museum, is situated in Croatia. It is associated with a famous cave site rich in internationally significant remains of Neanderthals and ice age fauna which have been researched for over a century. This contextual exhibition relies on a "simulation of life in the past" model. Modern interactive technology aims to create a sensual experience for the visitor. Because of its core content, the display embraces a rarely portrayed pan-European perspective on the past. The exhibition challenges the now obsolete paradigm which saw the Neanderthal lineage as marginal to mainstream human history. In Albania, where archaeological remains have been overtly manipulated by its leadership to advance territorial agendas, the Butrint Museum offers a holistic, in contrast to what was formerly a selective, approach to represent the past. In this small local museum, the focus is not overwhelmingly on the important large Roman seashore colony, Buthrotum, a UNESCO World Heritage Site since 1993; instead, even though the display genre remains effectively an artifact-oriented conservative one, a more balanced, *diachronic*,

narrative is presented which charts the many transformations that the locale underwent, from its modest status as an Iron Age settlement down to its strategic fortification by Venetian and Ottoman rulers.

Turkey currently invests much energy and funds in modernizing some of its leading archaeological museums (e.g., the Topkapi Palace, Instanbul); a comparable, yet on a much grander scale, reconceptualization of the past is clearly evident at the Museum of Anatolian Civilizations, Ankara. With the aim of validating the new, westernized, Turkish identity, this, the first museum of archaeology of Republican Turkey, was originally assembled (1938–1941) to "construct" a deep national, i.e., autochthonous, past by "acculturating" the remains of the Hittite civilization – an empire born and developed in Anatolia and with no "obvious" descendants (Gürol 2008). After the museum's renovation in the 1990s, an impressive array of artifact collections were often displayed in a "reconstruction" mode – that is, they were arranged in a manner that recreated how they were used in the past. The exhibition encompasses an amplified chronological scheme, from early prehistory to the early twentieth century. Due attention and a more even representation is now placed on the many other cultural manifestations – e.g., Phrygian, Lydian, Greek, Roman, Byzantine, Ottoman – that left their rich imprint on the vast expanses of this westernmost Asian peninsula. This dynamic institution is currently being rearranged.

The traumatic recent history of Cyprus and still unresolved partition of the island has prevented renovation of its archaeological museums on either side of the Green Line (Bounia and Stylianou-Lambert 2011). However, a site-specific museum innovative for its time (the 1990s) is located at Maa-Palaiokastro, in the remote southwest countryside near Paphos. Although this exhibition does not, for security reasons, hold collections of original artifacts, it does provide in its modern building an insightful outlook on everyday life at this Late Bronze settlement and the key-role this resource-rich island played in the wider trading and cultural networks throughout antiquity.

From the above eclectic survey, it becomes evident that there is immense potential for the future development of archaeological museums in Southeast Europe especially intellectually by disregarding old- or neo-nationalist modes of thought. In this portion of the Continent, which incontestably holds a deep and rich past, archaeological museums can and perhaps urgently need to set challenging goals by turning away from unproductive policies which have haunted the modern history of the area and to explore the *tremendous* cultural variability of the region, in time and space. Powerfully singular, archaic, medieval or other, selective or utopian narratives become all the less appealing in the increasingly competitive tourist industry on which these institutions increasingly rely upon for their very existence. Besides, any kind of culturally monolithic and simplistic museum narrative of the past entails dangers for the communities and citizens of today and jeopardizes their future. As some of the examples reviewed above demonstrate, archaeological museums in this diverse region can become bridging rather than dividing institutions of memory.

Southern Africa: Cultural Heritage Tourism Development and Management

Susan O. Keitumetse
Okavango Research Institute, University of Botswana, Maun, Botswana

Introduction

Cultural heritage tourism is travel that focuses on admiring and learning about historical landscapes, past monuments, cultural landscapes, archaeological sites, historical artifacts, and most of all the local communities who are hosts of these treasures that are sought for travel. These features and material culture can be situated in their places of origin, such as Egyptian pyramids, or can be packaged and placed in a museum setting, e.g., a hub of Smithsonian Museums in Washington DC, USA. The process of deliberate travel to and seeking of interpretation of these features adds to the tourism experience of these cultural and heritage landscapes and associated material culture.

Cultural heritage resources that sustain cultural heritage tourism are of two categories:

1. *Tangible* (UNESCO 1972) – These include among others archaeological artifacts as well as archaeo-historical sites, monuments, and landscapes.
2. *Intangible heritage* (UNESCO 2003) – These constitute cultural skills, knowledge, and expressions associated with material culture, i.e., the intellect that informs the production of tangible heritage.

The development of heritage tourism in southern Africa needs to be assessed through four key processes in order to come up with a balanced representation of heritage at any particular site:

1. The process of heritage knowledge production (i.e., placement of meanings and values associated with material culture, in a country). Read case study research on interpretation at Keitumetse (2016b)
2. Sociocultural, sociopolitical, and socioeconomic landscape within which heritage knowledge is identified, selected, and expressed through tourism
3. The broader context within which tourism developed and resulted in cultural and heritage tourism (cf. Keitumetse 2016d)
4. Extent of local community involvement and development – which in archaeology is represented by what is popularly referred to as public archaeology (Little 2005; Keitumetse 2016a)

Cultural heritage tourism commercializes historical events related to people's historical lives. Unlike safari tourism currently taking place in most of southern African countries, the use of cultural and heritage resources in an open-market setting requires more attention toward the sensitivity of the cultural resources. Conservation indicators that are specific to cultural and heritage resources are therefore necessary (Cf. Keitumetse 2016a, d).

Like the broader tourism, the origins of cultural heritage tourism in the south can be attributed to nineteenth-century European travel that inspired exotic travel to most regions including southern Africa. Particular to southern Africa, this travel was largely triggered by the advent of missionaries, ancient traders, and explorers seeking alternative trade routes, all of which exposed African communities and cultures to the outside world. Colonial anthropological research also played a significant role as it placed a spotlight on what came to be termed "exotic" cultures.

In post-nineteenth-century period, environmental protection awareness policies such as the 1972 World Heritage Convention and the 1987 World Convention on Environment and Development (WCED) resulted in natural resources tourism (safari tourism) that became dominant in African wilderness environments that were populated by people, some of whom had to be relocated to created wilderness and wildlife environmental spots. However, the formal incorporation of cultural heritage resources in safari tourism remained limited or haphazardly incorporated, if not neglected.

The twenty-first century has seen the development of concepts such as ecotourism (Drumm and Moore 2002), responsible tourism (cf. Revitt and Sanders 2002), and pro-poor tourism, all of whom are mistaken to represent cultural heritage tourism. Some of the aims of these concepts are to promote tourism that encourages direct interaction and responsibility toward local communities, thus exposing African local cultures to international visitors. However, of concern is the lack of attention accorded the management of cultural heritage resources as stand-alone products. Within the broader rural and local development studies, tourism is gradually being perceived as a medium through which the local "publics" (in archaeological heritage language) or local communities (in social development literature) represent and express themselves to a global world in order to acquire financial gain.

In sub-Saharan Africa, a prerequisite to selecting heritage for tourism is to analyze issues of ownership/affiliation identification, selection, and interpretation of heritage resources (Keitumetse 2016a, b). In addition, a broader theory of the concept of "community" and cultural resources use in tourism also has to be established.

In cultural heritage tourism, a balanced point of departure that considers political, social, economic, as well as cultural meanings and affiliations that are imbued within existing archaeological interpretations is necessary to balance presented identities. Case studies in Boxes 1 and 2 provide examples of issues to be considered in packaging cultural heritage resources for tourism in southern African contexts. Others are discussed in detail in a section below, under the heading "Key Issues/Current Debates."

In most cases, the tourism aspect of cultural heritage is not addressed by specific cultural heritage professionals from disciplines such as archaeology, but rather by business-based disciplines. In this regard, cultural resources become vulnerable to destruction as their conservation needs are not attended to.

Definition

Tourism is travel to places that can be termed "exotic" from the traveler's place of abode. Cultural heritage tourism is a branch of tourism that extends the symbolic value of cultural and heritage resources to economic significance. The extended value is however dependent on conservation of historical sites, archaeological remains, monuments, sites, and cultural landscapes. Archaeological and historical heritage tourism can take place in museums, interpretation facilities, in situ archaeological sites, and historical landscapes, among others.

Smith (1995) provides a summary of salient features that characterize definitions and descriptions of twentieth-century tourism within the mandate of the 1970 World Tourism Organization (UNWTO) as follows:

1937 – Key indicator was 24-h stay.
1950 – Inclusion of student on study tours as tourists and less than 24-h traveler called excursionist.
1963 – Distinction between tourists staying 24-h and those staying less recognized.
1967 – Distinction between tourists who stay overnight and those that do not was drawn as well as recognition of transit travelers as tourists.
1991 – International definitions of tourism emphasized and developed.
1993 – Tourism concepts at the center stage – identification and refining of these.

In addition to developments on tourism description and definition, The International Ecotourism Society (TIES) was launched in 1990 to guide and control tourism activities in ecologically sensitive areas. Ecotourism is defined as travel to pristine places to experience both environment and cultures of the people without jeopardizing opportunities for others to have similar experiences in the future – in other words, the sustainable aspect of travel. In 1997 TIES included "Ecotourism and community participation" as one of its operational principles which ultimately kick-started a process for recognition of local community with associated cultural and heritage resources.

The concept of *community participation* is significant in both conservation and tourism product interpretation. There are various definitions surrounding the use of the phrase "the public" and/or community in approaches toward cultural and heritage resources management. In cultural heritage literature, a community is composed of people residing in close proximity to a heritage site and has direct affiliation and emotional connection with the site, hence has acquired a significant level of commitment to the overall cultural landscape (Keitumetse 2005, 2009). In tourism literature, the generic term, "hosts," represents this group well. Within the development field, a community is composed of a group of people who share geographical affiliation and may or may not have historical ties to a particular cultural heritage.

On a more international scale, tourists represent "a public" or a "community" that is neither historically affiliated to a geographical space nor a particular form of heritage but acknowledge certain cultural heritage as significant enough to be visited, and enjoyed, hence placing tourism values on those. In protected areas of southern Africa, a consciously guided cultural/

archaeological heritage is yet to be established, and in this instance, the development of heritage tourism faces two options: adopt the existing notions of the public (local community) as per natural resources management processes or modify the existing to suit the needs of the relatively new field of cultural heritage resources management and tourism. While pondering on this dilemma, it is important to consider the public in the context within which each disciplinary research has developed.

Box 1 Botswana Case Study: Examples of Issues to Consider When Initiating Cultural Heritage for Tourism

Botswana: 1900–Present

Bechuanaland Protectorate became independent in 1966. Pre-independence archaeological heritage protection in the country included Proclamation No. 40, of 18 November 1911 cited as "The Bushmen Relics and Ancient Ruins Protection (Bechuanaland Protectorate)" – highlighting the Bushmen/San/Basarwa as a perceived "local community" at the time. This perception of "Bushmen" as the public in what later became heritage management emanated from South Africa where Bushmen rock art was protected from European expedition members who supposedly vandalized it for souvenir purposes as well as protection from resident communities who used the caves in which rock art was found for livestock rearing and shelter. Government of the Republic of South Africa, National Monuments Council (1970–1977).

The heritage "management" approach, as it were, prohibited the perceived "public" from interacting with tangible heritage. Emphasis on the *"Bushmen"* also indicates perception of whose heritage was selected and presented as well as by whom.

It appears that perception of the Bushmen as "ancient" perpetuated their image as a community that could not manage (select, interpret, and present) their heritage to visitors, a characteristic that still prevails to a certain extent in southern African heritage management to date. "Bushmen" heritage is currently managed by either NGOs or governments on their behalf (see Fig. 1 below).

The case study shows that whereas earlier focus on the Bushmen established a basic framework approach for public/local community recognition, their placement as passive participants rather than custodians of heritage has set a negative precedence that they are not empowered to lead a process of identification, selection, and presentation of their heritage through tourism. The question of who places tourism value on the San/Bushmen/Basarwa or any community, heritage and for what purpose becomes relevant. In developing heritage tourism, these

Southern Africa: Cultural Heritage Tourism Development and Management, Fig. 1 San/Bushmen of southern Africa depicted in international playing cards by other stakeholders

S

Box 1 Botswana Case Study: Examples of Issues to Consider When Initiating Cultural Heritage for Tourism (continued)

historical nuances become very significant in achieving an ethical and sustainable tourism product.

The most substantive archaeological legislation in present-day Botswana came into effect after the revision of the 1934 *Antiquities* Act, and it was named *The Monuments and Relics Act, 1970 chapter 59:03*. In contrast with the Bushmen Relics Act of 1911, any feature "...known or believed to have been erected, constructed or used before 1st June, 1902..." was considered of importance. This characteristic broadened the scope of the concept of the public to include those who were not represented in the 1911 and 1934 legislation. Three decades later, the 1970 Act has been revised and reenacted as the *Monuments and Relics Act 2001*, which is currently in operation.

Box 2 The Republic of South Africa Case Study: History of Cultural Heritage Legislation and the Development of Tourism Identities

The Republic of South Africa: 1900s–Present

A number of institutions have had either a general interest or a legal mandate for heritage management in RSA over the years. These are the South African National Society (1905–1934), the Historical Monuments Commission (1934–1969), and the National Monuments Council (1969–1999). Since the promulgation of the NHRA, heritage management has been restructured along the national, provincial, and local levels. The South African Heritage Resources Agency (2000–present) is currently tasked with the management of Grade I sites, while the Provincial Heritage Resources Authorities and Local Heritage Resource Authorities are responsible for Grade II and Grade III heritage sites, respectively. Historical accounts from these institutions highlight the events that shaped the selection, presentation, and representation of cultural heritage, some of which is currently used in cultural heritage tourism in the country. In the early 1900s, the South African National Society (1905–1934) was more biased on Bushmen heritage (cf. *The 1911 Bushmen Relics and Ancient Ruins Protection*). By the mid-1930s, focus shifted to the cultural heritage of European origin. This is well illustrated by the quote from van Riet Lowe who was the Secretary of the Historical Monuments Commission:

> The intrepid Portuguese navigators who originally discovered and explored our coast; the courageous and freedom-loving Dutch settlers who first made South Africa their home and braved the dangers of colonizing a remote and barbarous country; the Huguenots who for the sake of their ideals, sacrificed their all; and the British settlers, who assisted in colonizing the border districts and who gave us the institutions of democracy, including a free press. They have all left us a heritage which should serve as a nerve-ending source of inspiration to our growing nation... (Van Riet 1941: 08)

The narrow definition of heritage communities from the example above illustrates a common mistake by most heritage managers to fail to proactively inquire, prior to selection, about the type of heritage represented, by whom, and how (Figs. 1 and 2). An all-encompassing approach has to always be consciously sought.

Another aspect highlighted by this account is that which concerns the question of whose heritage. Since 1986, however, conceptualizations of public heritage in RSA legislation and practice broadened to encompass social inclusion. Heritages that "...constituted historical, aesthetic...

Southern Africa: Cultural Heritage Tourism Development and Management, Fig. 2 A cultural village setup where members of the local communities become employees hired to perform their cultural heritage aspects to tourists

Box 2 The Republic of South Africa Case Study: History of Cultural Heritage Legislation and the Development of Tourism Identities (continued)

value" (Annual report 18 1987: 03) were considered under the *War Graves and National Monuments Amendment Act of 1986* (Annual report 21 1990: 03). This 1986 legislation made allowance for a sub-committee which was formulated to coordinate the interpretation of historical sites in a way that encompassed and enhanced all types of community participation in rural areas of the Republic (Annual report 26 1994: 11).
